Subject: Comments on Draft Groundwater Sustainability Plan for Vina Subbasin
Date: Friday, October 15, 2021 10:24:32 AM
Attachments: [Public Comment Letter DraftGSP Vina.pdf](#)

ATTENTION: This message originated from outside **Butte County**. Please exercise judgment before opening attachments, clicking on links, or replying.

Hello,

I am writing on behalf of Audubon California, Clean Water Action, Clean Water Fund, Local Government Commission, The Nature Conservancy, American Rivers and Union of Concerned Scientists with the attached comments on the draft Groundwater Sustainability Plan for this basin.

We know that SGMA plan development and implementation is a major undertaking, and we want every basin to be successful. We would be happy to meet with you to discuss our evaluation as you finalize your Plan for submittal to DWR. Feel free to contact us at ngos.sgma@gmail.com for more information or to schedule a conversation.

Sincerely,

J. Pablo Ortiz-Partida, Ph.D.
Western States Climate and Water Scientist
Union of Concerned Scientists

Re: Public Comment Letter for Vina Subbasin Draft GSP

Dear Christina Buck,

On behalf of the above-listed organizations, we appreciate the opportunity to comment on the Draft Groundwater Sustainability Plan (GSP) for the Vina Subbasin being prepared under the Sustainable Groundwater Management Act (SGMA). Our organizations are deeply engaged in and committed to the successful implementation of SGMA because we understand that groundwater is critical for the resilience of California's water portfolio, particularly in light of changing climate. Under the requirements of SGMA, Groundwater Sustainability Agencies (GSAs) must consider the interests of all beneficial uses and users of groundwater, such as domestic well owners, environmental users, surface water users, federal government, California Native American tribes and disadvantaged communities (Water Code 10723.2).

As stakeholder representatives for beneficial users of groundwater, our GSP review focuses on how well disadvantaged communities, drinking water users, tribes, climate change, and the environment were addressed in the GSP. While we appreciate that some basins have consulted us directly via focus groups, workshops, and working groups, we are providing public comment letters to all GSAs as a means to engage in the development of 2022 GSPs across the state. Recognizing that GSPs are complicated and resource intensive to develop, the intention of this letter is to provide constructive stakeholder feedback that can improve the GSP prior to submission to the State.

Based on our review, we have significant concerns regarding the treatment of key beneficial users in the Draft GSP and consider the GSP to be **insufficient** under SGMA. We highlight the following findings:

1. Beneficial uses and users **are not sufficiently** considered in GSP development.
 - a. Human Right to Water considerations **are not sufficiently** incorporated.
 - b. Public trust resources **are not sufficiently** considered.
 - c. Impacts of Minimum Thresholds, Measurable Objectives and Undesirable Results on beneficial uses and users **are not sufficiently** analyzed.
2. Climate change **is not sufficiently** considered.
3. Data gaps **are not sufficiently** identified and the GSP **does not have a plan** to eliminate them.
4. Projects and Management Actions **do not sufficiently consider** potential impacts or benefits to beneficial uses and users.

Our specific comments related to the deficiencies of the Vina Subbasin Draft GSP along with recommendations on how to reconcile them, are provided in detail in **Attachment A**.

Please refer to the enclosed list of attachments for additional technical recommendations:

- Attachment A** GSP Specific Comments
- Attachment B** SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users
- Attachment C** Freshwater species located in the basin
- Attachment D** The Nature Conservancy's "Identifying GDEs under SGMA: Best Practices for using the NC Dataset"
- Attachment E** Maps of representative monitoring sites in relation to key beneficial users

Thank you for fully considering our comments as you finalize your GSP.

Best Regards,

Ngodoo Atume

Attachment A

Specific Comments on the Vina Subbasin Draft Groundwater Sustainability Plan

1. Consideration of Beneficial Uses and Users in GSP development

Consideration of beneficial uses and users in GSP development is contingent upon adequate identification and engagement of the appropriate stakeholders. The (A) identification, (B) engagement, and (C) consideration of disadvantaged communities, drinking water users, tribes, groundwater dependent ecosystems, streams, wetlands, and freshwater species are essential for ensuring the GSP integrates existing state policies on the Human Right to Water and the Public Trust Doctrine.

A. Identification of Key Beneficial Uses and Users

Disadvantaged Communities, Drinking Water Users, and Tribes

The identification of Disadvantaged Communities (DACs) and drinking water users is **insufficient**. The GSP provides information on DACs, including identification by name and location on a map. However, the plan fails to clearly document the population of each DAC. In addition, the GSP fails to include the population dependent on groundwater as their source of drinking water in the subbasin.

Appendix 1-D of the GSP states that the Mechoopda Indian Tribe of Chico Rancheria is located in Vina Subbasin. The location and map of tribal lands, however, is not provided.

While the plan provides a density map of domestic wells in the subbasin (Figure 1-9), the GSP fails to provide depth of these wells (such as minimum well depth, average well depth, or depth range) within the subbasin.

These missing elements are required for the GSAs to fully understand the specific interests and water demands of these beneficial users, and to support the consideration of beneficial users in the development of sustainable management criteria and selection of projects and management actions.

RECOMMENDATIONS

- Provide the population of each identified DAC. Identify the sources of drinking water for DAC members, including an estimate of how many people rely on groundwater (e.g., domestic wells, state small water systems, and public water systems).
- Provide a map of tribal lands and describe the tribal population within the subbasin.
- Include a map showing domestic well locations and average well depth across the subbasin.

Interconnected Surface Waters

The identification of Interconnected Surface Waters (ISWs) is **insufficient**, due to lack of supporting information provided for the ISW analysis. GSP Section 2.2.6.2 (Evaluation of Surface Water Connectivity) describes well locations, proximity to streams, and screening depths that were used to evaluate surface water connectivity. However, Section 2.2.6.3 (Estimates of Surface

Water Connection Based on BBGM [Butte Basin Groundwater Model]) does not describe the data used in the BBGM model, such as the groundwater level monitoring well data and stream gauge data that were incorporated into the model. Additionally, no description was provided of the temporal (seasonal and interannual) variability of the data used to calibrate the model. This information should be provided in the GSP to support the conclusions presented.

Figure 2-26 presents a map of stream reaches in the subbasin, showing the percentage of months of either a gaining or losing condition in the subbasin as predicted by the BBGM model. Based on the color coding it appears that all surface water is considered to be connected, but the percentage of connection for many of the upland streams and tributaries in the subbasin are labeled 0%. Therefore it is not clear what is an ISW and what is not based on this map. We recommend that these labels are clarified in the text so it is more clear which stream segments are retained as ISWs or potential ISWs in the GSP and to include a description of the logic behind determining which reaches are and are not ISWs. Note the regulations [23 CCR §351(o)] define ISW as “surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted”. “At any point” has both a spatial and temporal component. Even short durations of interconnections of groundwater and surface water can be crucial for surface water flow and supporting environmental users of groundwater and surface water.

RECOMMENDATIONS

- Describe the legend labels used on Figure 2-26 in the GSP text to make clear which stream segments are retained as ISWs or potential ISWs in the GSP.
- Further describe the groundwater elevation data and stream flow data used in the BBGM analysis. Ensure depth-to-groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) are used to determine the range of depth and capture the variability in environmental conditions inherent in California’s climate.
- To confirm and illustrate the results of the groundwater modeling, overlay the stream reaches shown on Figure 2-26 with depth-to-groundwater contour maps to illustrate groundwater depths and the groundwater gradient near the stream reaches. Show the location of groundwater wells used in the analysis.
- For the depth-to-groundwater contour maps, use the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a Digital Elevation Model (DEM) to estimate depth-to-groundwater contours across the landscape. This will provide accurate contours of depth to groundwater along streams and other land surface depressions where GDEs are commonly found.
- Describe data gaps for the ISW analysis in the ISW section, in addition to the discussion in the HCM section (2.1.9.2). On Figure 2-26, include reaches with data gaps as potential ISWs.

Groundwater Dependent Ecosystems

The identification of Groundwater Dependent Ecosystems (GDEs) is **insufficient**. The GSP does not discuss how the Natural Communities Commonly Associated with Groundwater dataset (NC dataset) was verified with the use of groundwater data from the shallow aquifer. Without an analysis of groundwater data to verify the NC dataset polygons, it will be difficult or impossible to adequately monitor and manage the subbasin's GDEs throughout GSP implementation.

The GSP took initial steps to identify and map GDEs using the NC dataset and other sources. However, we found that some mapped features in the NC dataset were improperly disregarded. NC dataset polygons were incorrectly removed in areas adjacent to irrigated fields or due to the presence of surface water supplies. However, this removal criteria is flawed since GDEs, in addition to groundwater, can rely on multiple water sources – including shallow groundwater receiving inputs from irrigation return flow from nearby irrigated fields – simultaneously and at different temporal/spatial scales. NC dataset polygons adjacent to irrigated land or surface water supplies can still potentially be reliant on shallow groundwater aquifers, and therefore should not be removed solely based on their proximity to irrigated fields or surface water.

The GSP did not discuss the flora or fauna species present in the subbasin's GDEs, except to acknowledge the presence of Valley oak (*Quercus lobata*) in the subbasin. We commend the GSAs for retaining all Valley oak polygons in the NC dataset based on the recognition that they can access groundwater at deeper depths.

RECOMMENDATIONS

- Provide a comprehensive set of maps for the subbasin's GDEs. For example, provide a map of the NC Dataset. On the map, label polygons retained, removed, or added to/from the NC dataset (include the removal reason if polygons are not considered potential GDEs, or include the data source if polygons are added). Discuss how local groundwater data was used to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer. Refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.
- Use depth-to-groundwater data from multiple seasons and water year types (e.g., wet, dry, average, drought) to determine the range of depth to groundwater around NC dataset polygons. We recommend that a baseline period (10 years from 2005 to 2015) be established to characterize groundwater conditions over multiple water year types. Refer to Attachment D of this letter for best practices for using local groundwater data to verify whether polygons in the NC Dataset are supported by groundwater in an aquifer.
- Provide depth-to-groundwater contour maps, noting the best practices presented in Attachment D. Specifically, ensure that the first step is contouring groundwater elevations, and then subtracting this layer from land surface elevations from a DEM to estimate depth-to-groundwater contours across the landscape.
- If insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons as "Potential GDEs" in the GSP until data gaps are reconciled in the monitoring network. It is not clear from the description in the GSP whether NC dataset polygons labeled as 'Not Likely a GDE' are retained as potential GDEs.

- Include an inventory of the fauna and flora present within the subbasin's GDEs (see Attachment C of this letter for a list of freshwater species located in the Vina Subbasin). Note any threatened or endangered species.

Native Vegetation and Managed Wetlands

Native vegetation and managed wetlands are water use sectors that are required^{1,2} to be included in the water budget. The integration of these ecosystems into the water budget is **sufficient** because the groundwater demands of native vegetation and managed wetlands are included in the historical, current, and projected water budgets. Additional clarification is needed on why the current and projected water demands for managed wetlands are approximately half the water demands represented in the historical water budget (Table 2-7). These ecosystems will have continued or higher water needs in the future to provide habitat for migratory birds.

RECOMMENDATION

- Revisit the current and projected water demands for managed wetlands, which are represented in the GSP as approximately half the historical water demands. Provide a justification for these water budget values for managed wetlands in Table 2-7. Also, provide the water budget model documentation referenced in the GSP (BCDWRC 2021).

B. Engaging Stakeholders

Stakeholder Engagement during GSP development

Stakeholder engagement during GSP development is **insufficient**. SGMA's requirement for public notice and engagement of stakeholders³ is not fully met by the description in the Communication and Engagement Plan (Appendix 1-D).

The Communication and Engagement Plan documents representation of tribal and environmental interests during the GSP development process. A tribal staff member from the Mechoopda Indian Tribe of Chico Rancheria has represented the tribe during GSP development and participates as a member of the Vina GSA Management Committee. Additionally, there is an environmental representative on the GSA Advisory Committee.

However, we note the following deficiencies with the overall stakeholder engagement process:

- The opportunities for public involvement and engagement with DACs and drinking water users are described in very general terms. They include meetings open to the public, including GSA Board meetings, meetings in conjunction with the Reclamation District,

¹ "Water use sector' refers to categories of water demand based on the general land uses to which the water is applied, including urban, industrial, agricultural, managed wetlands, managed recharge, and native vegetation." [23 CCR §351(a)]

² "The water budget shall quantify the following, either through direct measurements or estimates based on data: (3) Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow." [23 CCR §354.18]

³ "A communication section of the Plan shall include a requirement that the GSP identify how it encourages the active involvement of diverse social, cultural, and economic elements of the population within the basin." [23 CCR §354.10(d)(3)]

subbasin-wide technical meetings, Farm Bureau Water Forum meeting, City of Chico meetings, and Regional Water Management Group meetings. No specific outreach targeted to DACs is described in the GSP.

- The GSP describes an Engagement Matrix in Appendix 1-F for engaging with DACs, tribes, and environmental stakeholders through the implementation phase. However, Appendix 1-F was not included in the Draft GSP.

RECOMMENDATION

- In the Communication and Engagement Plan, describe active and targeted outreach to engage DAC members, drinking water users, environmental stakeholders and consultation to tribes through the GSP development and implementation phases. Refer to Attachment B for specific recommendations on how to actively engage stakeholders during all phases of the GSP process.

C. Considering Beneficial Uses and Users When Establishing Sustainable Management Criteria and Analyzing Impacts on Beneficial Uses and Users

The consideration of beneficial uses and users when establishing sustainable management criteria (SMC) is **insufficient**. The consideration of potential impacts on all beneficial users of groundwater in the basin are required when defining undesirable results⁴ and establishing minimum thresholds.^{5,6}

Disadvantaged Communities and Drinking Water Users

For chronic lowering of groundwater levels, the GSP discusses minimum thresholds impact on domestic wells (see Section 3.3.2 Minimum Thresholds). The GSP states (p. 103): *“In recent years, Butte County has documented a number of domestic wells that have “gone dry,” meaning groundwater levels have fallen below the depth of the well installation and/or pump. This occurred during summer months of recent drought years and heightened concern among some stakeholders. As a result, domestic well reliability and protection are the focus of the Groundwater Levels MT.”* The GSP discusses the use of the DWR domestic well database and sets minimum threshold levels protective of domestic wells by establishing a representative zone for each RMS well.

The GSP does not however, sufficiently describe or analyze direct or indirect impacts on DACs or tribes when defining undesirable results, nor does it describe how the existing minimum threshold groundwater levels are consistent with avoiding undesirable results to DACs and tribes in the subbasin.

⁴ “The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results.” [23 CCR §354.26(b)(3)]

⁵ “The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests.” [23 CCR §354.28(b)(4)]

⁶ “The description of minimum thresholds shall include [...] how state, federal, or local standards relate to the relevant sustainability indicator. If the minimum threshold differs from other regulatory standards, the agency shall explain the nature of and the basis for the difference.” [23 CCR §354.28(b)(5)]

For degraded water quality, salinity is the only constituent of concern (COC) for which SMC are established in the Vina Subbasin. The minimum threshold is set to the upper limit of the Secondary Maximum Contaminant Level (SMCL) for specific conductance based on the state secondary drinking water standards. The GSP states (p. 108): *“Other constituents, as discussed in Section 2.2.4, are managed through existing management and regulatory programs within the Subbasin, such as the Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS) and the Irrigated Lands Regulatory Program (ILRP), which focus on improving water quality by managing septic and agricultural sources of salinity and nutrients. Additionally, point-source contaminants are managed and regulated through a variety of programs by the Regional Water Quality Control Board (RWQCB), Department of Toxic Substances Control (DTSC), and the U.S. Environmental Protection Agency (EPA).”* However, SMC should be established for all COCs including chemicals of emerging concern (CEC) in the subbasin impacted or exacerbated by groundwater use and/or management, in addition to coordinating with water quality regulatory programs.

The GSP only includes a very general discussion of impacts to drinking water users when defining undesirable results and evaluating the impacts of proposed minimum thresholds. The GSP does not, however, mention or discuss direct and indirect impacts on DACs, drinking water users or tribes when defining undesirable results for degraded water quality, nor does it evaluate the cumulative or indirect impacts of proposed minimum thresholds on beneficial users.

RECOMMENDATIONS
<p>Chronic Lowering of Groundwater Levels</p> <ul style="list-style-type: none"> Describe direct and indirect impacts on DACs and tribes when describing undesirable results and defining minimum thresholds for chronic lowering of groundwater levels (in addition to describing impacts to drinking water users). <p>Degraded Water Quality</p> <ul style="list-style-type: none"> Describe direct and indirect impacts on drinking water users, DACs, and tribes when defining undesirable results for degraded water quality. For specific guidance on how to consider these users, refer to “Guide to Protecting Water Quality Under the Sustainable Groundwater Management Act.”⁷ Evaluate the cumulative or indirect impacts of proposed minimum thresholds for degraded water quality on drinking water users, DACs, and tribes. Set minimum thresholds and measurable objectives for all water quality constituents within the subbasin that can be impacted and/or exacerbated as a result of groundwater use or groundwater management. Ensure they align with drinking water standards⁸.

⁷ Guide to Protecting Water Quality under the Sustainable Groundwater Management Act https://d3n8a8pro7vhmx.cloudfront.net/communitywatercenter/pages/293/attachments/original/1559328858/Guide_to_Protecting_Drinking_Water_Quality_Under_the_Sustainable_Groundwater_Management_Act.pdf?1559328858.

⁸ “Degraded Water Quality [...] collect sufficient spatial and temporal data from each applicable principal aquifer to determine groundwater quality trends for water quality indicators, as determined by the Agency, to address known water quality issues.” [23 CCR §354.34(c)(4)]

Groundwater Dependent Ecosystems and Interconnected Surface Waters

Sustainable management criteria for chronic lowering of groundwater levels provided in the GSP do not consider potential impacts to environmental beneficial users. The GSP neither describes nor analyzes direct or indirect impacts on environmental users of groundwater when defining undesirable results. This is problematic because without identifying potential impacts to GDEs, minimum thresholds may compromise, or even destroy, these environmental beneficial users. Since GDEs are present in the subbasin, they must be considered when developing SMC for chronic lowering of groundwater levels.

The GSP recognizes a data gap with respect to the interconnected surface water SMC. The GSP states (p. 113): *“The GSAs in the Vina Subbasin intend to further evaluate this SMC to avoid undesirable results to aquatic ecosystems and GDEs. To that end, an Interconnected Surface Water SMC framework has been developed for the GSP as described below. This framework will guide future data collection efforts to fill data gaps, either as part of GSP projects and management actions or plan implementation.”*

While the data gap is being filled, the SMC for depletion of interconnected surface water are established by proxy using groundwater levels. The GSP states (p. 115): *“Therefore, at this time, Groundwater Levels SMC are used by proxy and the MT for interconnected surface water is the same as for groundwater levels: Two RMS wells reach their MT for two consecutive non-dry year-types.”* However, no analysis or discussion is presented to describe how the SMC will affect GDEs, or the impact of these minimum thresholds on GDEs in the subbasin. Furthermore, the GSP makes no attempt to evaluate the impacts of the proposed minimum threshold on environmental beneficial users of surface water. The GSP does not explain how the chosen minimum thresholds and measurable objectives avoid significant and unreasonable effects on surface water beneficial users in the subbasin, such as increased mortality and inability to perform key life processes (e.g., reproduction, migration).

RECOMMENDATIONS

- Define chronic lowering of groundwater SMC directly for environmental beneficial users of groundwater. When defining undesirable results for chronic lowering of groundwater levels, provide specifics on what biological responses (e.g., extent of habitat, growth, recruitment rates) would best characterize a significant and unreasonable impact to GDEs. Undesirable results to environmental users occur when ‘significant and unreasonable’ effects on beneficial users are caused by one of the sustainability indicators (i.e., chronic lowering of groundwater levels, degraded water quality, or depletion of interconnected surface water). Thus, potential impacts on environmental beneficial uses and users need to be considered when defining undesirable results⁹ in the subbasin. Defining undesirable results is the crucial first step before the minimum thresholds¹⁰ can be determined.
- When establishing SMC for the basin, consider that the SGMA statute [Water Code §10727.4(l)] specifically calls out that GSPs should include “impacts on groundwater dependent ecosystems”.

⁹ “The description of undesirable results shall include [...] potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results”. [23 CCR §354.26(b)(3)]

¹⁰ The description of minimum thresholds shall include [...] how minimum thresholds may affect the interests of beneficial uses and users of groundwater or land uses and property interests.” [23 CCR §354.28(b)(4)]

- When defining undesirable results for depletion of interconnected surface water, include a description of potential impacts on instream habitats within ISWs when minimum thresholds in the subbasin are reached¹¹. The GSP should confirm that minimum thresholds for ISWs avoid adverse impacts to environmental beneficial users of interconnected surface waters as these environmental users could be left unprotected by the GSP. These recommendations apply especially to environmental beneficial users that are already protected under pre-existing state or federal law^{6,12}.

2. Climate Change

The SGMA statute identifies climate change as a significant threat to groundwater resources and one that must be examined and incorporated in the GSPs. The GSP Regulations¹³ require integration of climate change into the projected water budget to ensure that projects and management actions sufficiently account for the range of potential climate futures.

The integration of climate change into the projected water budget is **insufficient**. The GSP incorporates climate change into the projected water budget using DWR change factors for 2030 and 2070. However, the plan does not consider multiple climate scenarios (e.g., the 2070 extremely wet and extremely dry climate scenarios) in the projected water budget. The GSP should clearly and transparently incorporate the extremely wet and dry scenarios provided by DWR into projected water budgets or select more appropriate extreme scenarios for the subbasin. While these extreme scenarios may have a lower likelihood of occurring, their consequences could be significant, therefore they should be included in groundwater planning.

The GSP includes climate change into key inputs (e.g., precipitation, evapotranspiration, and surface water flow) of the projected water budget. However, the sustainable yield is based on historic pumping rates instead of the projected water budget with climate change incorporated. If the water budgets are incomplete, including the omission of extremely wet and dry scenarios, and sustainable yield is not calculated based on climate change projections, then there is increased uncertainty in virtually every subsequent calculation used to plan for projects, derive measurable objectives, and set minimum thresholds. Plans that do not adequately include climate change projections may underestimate future impacts on vulnerable beneficial users of groundwater such as ecosystems, DACs, tribes, and domestic well owners.

¹¹ “The minimum threshold for depletions of interconnected surface water shall be the rate or volume of surface water depletions caused by groundwater use that has adverse impacts on beneficial uses of the surface water and may lead to undesirable results.” [23 CCR §354.28(c)(6)]

¹² Rohde MM, Seapy B, Rogers R, Castañeda X, editors. 2019. Critical Species LookBook: A compendium of California’s threatened and endangered species for sustainable groundwater management. The Nature Conservancy, San Francisco, California. Available at: https://groundwaterresourcehub.org/public/uploads/pdfs/Critical_Species_LookBook_91819.pdf

¹³ “Each Plan shall rely on the best available information and best available science to quantify the water budget for the basin in order to provide an understanding of historical and projected hydrology, water demand, water supply, land use, population, climate change, sea level rise, groundwater and surface water interaction, and subsurface groundwater flow.” [23 CCR §354.18(e)]

RECOMMENDATIONS

- Integrate climate change, including extremely wet and dry scenarios, into all elements of the projected water budget to form the basis for development of sustainable management criteria and projects and management actions.
- Calculate sustainable yield based on the projected water budget with climate change incorporated.
- Incorporate climate change scenarios into projects and management actions.

3. Data Gaps

The consideration of beneficial users when establishing monitoring networks is **insufficient**, due to lack of specific plans to increase the Representative Monitoring Sites (RMSs) in the monitoring network that represent water quality conditions and shallow groundwater elevations around DACs, domestic wells, tribes, GDEs, and ISWs in the subbasin.

Figure 4-5 (Groundwater Level RMS Wells) and Figure 4-6 (Water Quality RMS Wells) show that no monitoring wells are located across portions of the subbasin near DACs, domestic wells, and tribes (see maps provided in Attachment E). Beneficial users of groundwater may remain unprotected by the GSP without adequate monitoring and identification of data gaps in the shallow aquifer. The Plan therefore fails to meet SGMA's requirements for the monitoring network¹⁴.

The GSP provides some discussion of data gaps for GDEs and ISWs in Sections 4.10 (Network Assessment and Improvements) and Section 6.1.3 (Data Analysis), however does not provide specific plans, such as locations or a timeline, to fill the data gaps.

RECOMMENDATIONS

- Provide maps that overlay current and proposed monitoring well locations with the locations of DACs, domestic wells, tribes, GDEs, and ISWs to clearly identify potentially impacted areas. Increase the number of RMSs in the shallow aquifer across the subbasin as needed to adequately monitor all groundwater condition indicators. Prioritize proximity to DACs, domestic wells, tribes, and GDEs when identifying new RMSs.
- Describe biological monitoring that can be used to assess the potential for significant and unreasonable impacts to GDEs or ISWs due to groundwater conditions in the subbasin.

¹⁴ "The monitoring network objectives shall be implemented to accomplish the following: [...] (2) Monitor impacts to the beneficial uses or users of groundwater." [23 CCR §354.34(b)(2)]

4. Addressing Beneficial Users in Projects and Management Actions

The consideration of beneficial users when developing projects and management actions is **insufficient**, due to the failure to completely identify benefits or impacts of identified projects and management actions, including water quality impacts, to key beneficial users of groundwater such as GDEs, aquatic habitats, surface water users, DACs, drinking water users, and tribes. Therefore, potential project and management actions may not protect these beneficial users. Groundwater sustainability under SGMA is defined not just by sustainable yield, but by the avoidance of undesirable results for *all* beneficial users.

The GSP includes projects and management actions with explicit benefits to the environment. The plan also includes a domestic well mitigation program. However, the mitigation program is described as a potential project instead of a proposed project that will be implemented within the GSP planning horizon.

RECOMMENDATIONS

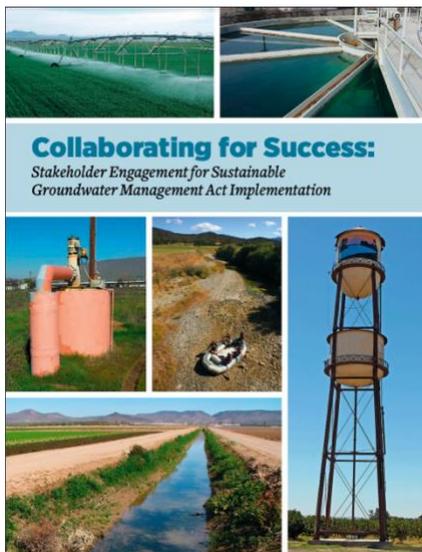

- Clarify the planning horizon of the described domestic well mitigation program to ensure that it will proactively monitor and protect drinking water wells through GSP implementation. Refer to Attachment B for specific recommendations on how to implement a drinking water well mitigation program.
- For DACs and domestic well owners, include a discussion of whether potential impacts to water quality from projects and management actions could occur and how the GSAs plans to mitigate such impacts.
- Recharge ponds, reservoirs, and facilities for managed aquifer recharge can be designed as multiple-benefit projects to include elements that act functionally as wetlands and provide a benefit for wildlife and aquatic species. For guidance on how to integrate multi-benefit recharge projects into your GSP, refer to the “Multi-Benefit Recharge Project Methodology Guidance Document”¹⁵.
- Develop management actions that incorporate climate and water delivery uncertainties to address future water demand and prevent future undesirable results.

¹⁵ The Nature Conservancy. 2021. Multi-Benefit Recharge Project Methodology for Inclusion in Groundwater Sustainability Plans. Sacramento. Available at: <https://groundwaterresourcehub.org/sgma-tools/multi-benefit-recharge-project-methodology-guidance/>

Attachment B

SGMA Tools to address DAC, drinking water, and environmental beneficial uses and users

Stakeholder Engagement and Outreach

Clean Water Action, Community Water Center and Union of Concerned Scientists developed a guidance document called [Collaborating for success: Stakeholder engagement for Sustainable Groundwater Management Act Implementation](#). It provides details on how to conduct targeted and broad outreach and engagement during Groundwater Sustainability Plan (GSP) development and implementation. Conducting a targeted outreach involves:

- Developing a robust Stakeholder Communication and Engagement plan that includes outreach at frequented locations (schools, farmers markets, religious settings, events) across the plan area to increase the involvement and participation of disadvantaged communities, drinking water users and the environmental stakeholders.
- Providing translation services during meetings and technical assistance to enable easy participation for non-English speaking stakeholders.
- GSP should adequately describe the process for requesting input from beneficial users and provide details on how input is incorporated into the GSP.

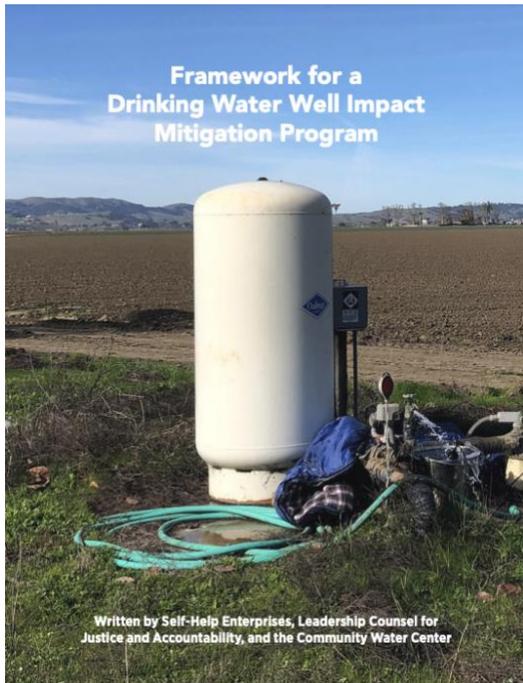

The Human Right to Water

Human Right To Water Scorecard for the Review of Groundwater Sustainability Plans

Review Criteria <i>(All Indicators Must be Present in Order to Protect the Human Right to Water)</i>		Yes/No
A Plan Area		
1	Does the GSP identify, describe, and provide maps of all of the following beneficial users in the GSA area? ²⁵ a. Disadvantaged Communities (DACs). b. Tribes. c. Community water systems. d. Private well communities.	
2	Land use policies and practices ²⁶ Does the GSP review all relevant policies and practices of land use agencies which could impact groundwater resources? These include but are not limited to the following: a. Water use policies General Plans and local land use and water planning documents b. Plans for development and zoning. c. Processes for permitting activities which will increase water consumption	
B Basin Setting (Groundwater Conditions and Water Budget)		
1	Does the groundwater level conditions section include past and current drinking water supply issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities?	
2	Does the groundwater quality conditions section include past and current drinking water quality issues of domestic well users, small community water systems, state small water systems, and disadvantaged communities, including public water wells that had or have MCLs exceedances? ²⁷	
3	Does the groundwater quality conditions section include a review of all contaminants with primary drinking water standards known to exist in the GSP area, as well as hexavalent chromium, and PFOs/PFOAs? ²⁸	
4	Incorporating drinking water needs into the water budget. ²⁹ Does the Future/Projected Water Budget section explicitly include both the current and projected future drinking water needs of communities on domestic wells and community water systems (including but not limited to infill development and communities' plans for infill development,	

The [Human Right to Water Scorecard](#) was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid Groundwater Sustainability Agencies (GSAs) in prioritizing drinking water needs in SGMA. The scorecard identifies elements that must exist in GSPs to adequately protect the Human Right to Drinking water.

Drinking Water Well Impact Mitigation Framework

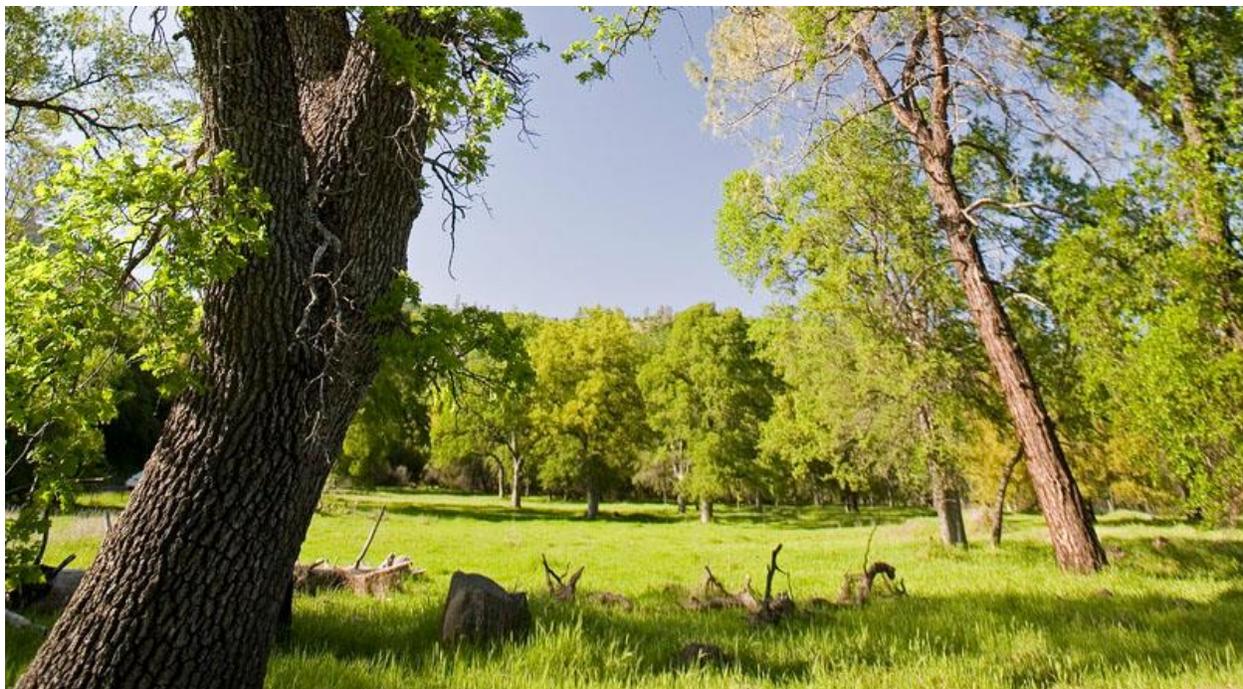

The [Drinking Water Well Impact Mitigation Framework](#) was developed by Community Water Center, Leadership Counsel for Justice and Accountability and Self Help Enterprises to aid GSAs in the development and implementation of their GSPs. The framework provides a clear roadmap for how a GSA can best structure its data gathering, monitoring network and management actions to proactively monitor and protect drinking water wells and mitigate impacts should they occur.

Groundwater Resource Hub

The Nature Conservancy has developed a suite of tools based on best available science to help GSAs, consultants, and stakeholders efficiently incorporate nature into GSPs. These tools and resources are available online at GroundwaterResourceHub.org. The Nature Conservancy's tools and resources are intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Rooting Depth Database

The [Plant Rooting Depth Database](#) provides information that can help assess whether groundwater-dependent vegetation are accessing groundwater. Actual rooting depths will depend on the plant species and site-specific conditions, such as soil type and

availability of other water sources. Site-specific knowledge of depth to groundwater combined with rooting depths will help provide an understanding of the potential groundwater levels are needed to sustain GDEs.

How to use the database

The maximum rooting depth information in the Plant Rooting Depth Database is useful when verifying whether vegetation in the Natural Communities Commonly Associated with Groundwater ([NC Dataset](#)) are connected to groundwater. A 30 ft depth-to-groundwater threshold, which is based on averaged global rooting depth data for phreatophytes¹, is relevant for most plants identified in the NC Dataset since most plants have a max rooting depth of less than 30 feet. However, it is important to note that deeper thresholds are necessary for other plants that have reported maximum root depths that exceed the averaged 30 feet threshold, such as valley oak (*Quercus lobata*), Euphrates poplar (*Populus euphratica*), salt cedar (*Tamarix spp.*), and shadescale (*Atriplex confertifolia*). The Nature Conservancy advises that the reported max rooting depth for these deeper-rooted plants be used. For example, a depth-to-groundwater threshold of 80 feet should be used instead of the 30 ft threshold, when verifying whether valley oak polygons from the NC Dataset are connected to groundwater. It is important to re-emphasize that actual rooting depth data are limited and will depend on the plant species and site-specific conditions such as soil and aquifer types, and availability to other water sources.

The Plant Rooting Depth Database is an Excel workbook composed of four worksheets:

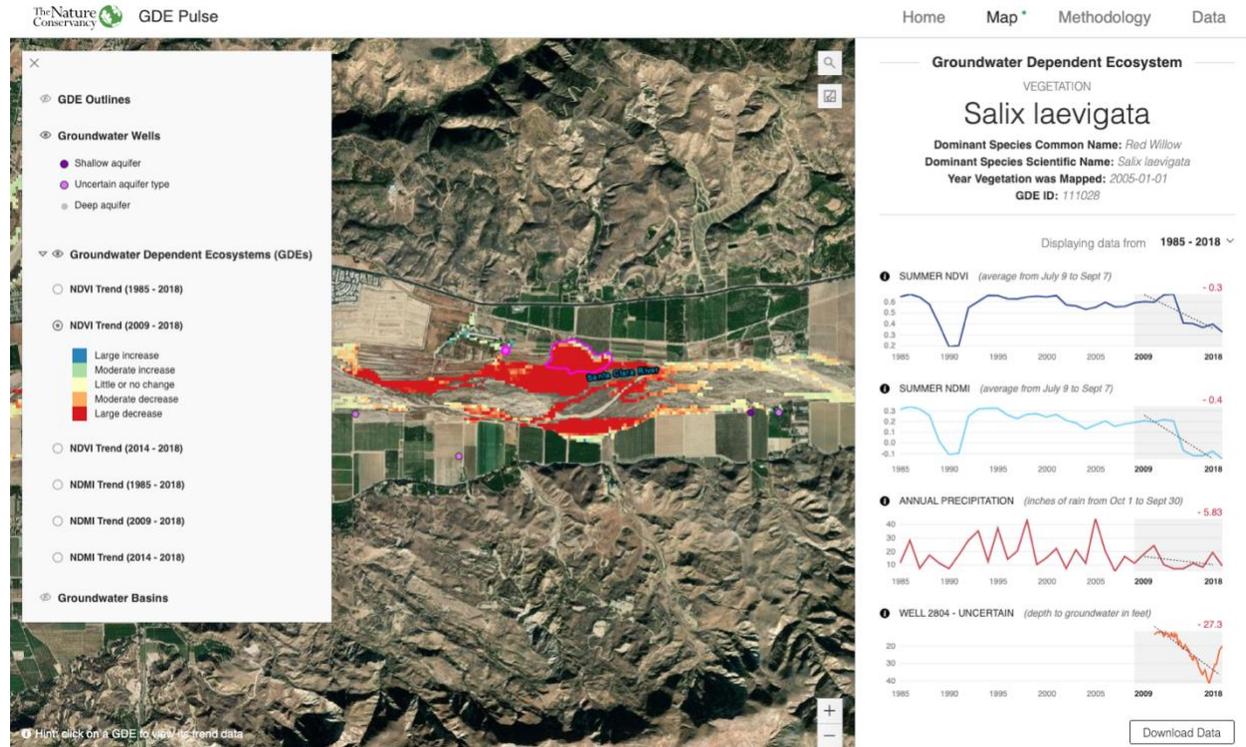

1. California phreatophyte rooting depth data (included in the NC Dataset)
2. Global phreatophyte rooting depth data
3. Metadata
4. References

How the database was compiled

The Plant Rooting Depth Database is a compilation of rooting depth information for the groundwater-dependent plant species identified in the NC Dataset. Rooting depth data were compiled from published scientific literature and expert opinion through a crowdsourcing campaign. As more information becomes available, the database of rooting depths will be updated. Please [Contact Us](#) if you have additional rooting depth data for California phreatophytes.

¹ Canadell, J., Jackson, R.B., Ehleringer, J.B. et al. 1996. Maximum rooting depth of vegetation types at the global scale. *Oecologia* 108, 583–595. <https://doi.org/10.1007/BF00329030>

GDE Pulse

[GDE Pulse](#) is a free online tool that allows Groundwater Sustainability Agencies to assess changes in groundwater dependent ecosystem (GDE) health using satellite, rainfall, and groundwater data. Remote sensing data from satellites has been used to monitor the health of vegetation all over the planet. GDE pulse has compiled 35 years of satellite imagery from NASA's Landsat mission for every polygon in the Natural Communities Commonly Associated with Groundwater Dataset. The following datasets are available for downloading:

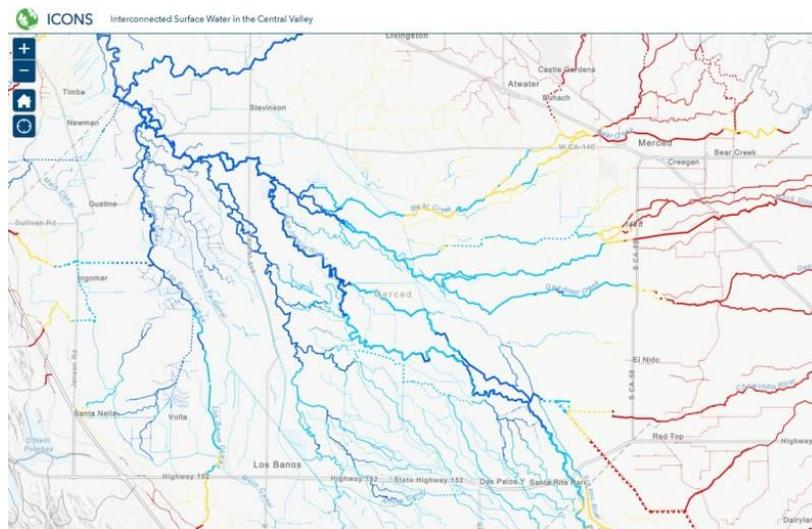

Normalized Difference Vegetation Index (NDVI) is a satellite-derived index that represents the greenness of vegetation. Healthy green vegetation tends to have a higher NDVI, while dead leaves have a lower NDVI. We calculated the average NDVI during the driest part of the year (July - Sept) to estimate vegetation health when the plants are most likely dependent on groundwater.

Normalized Difference Moisture Index (NDMI) is a satellite-derived index that represents water content in vegetation. NDMI is derived from the Near-Infrared (NIR) and Short-Wave Infrared (SWIR) channels. Vegetation with adequate access to water tends to have higher NDMI, while vegetation that is water stressed tends to have lower NDMI. We calculated the average NDVI during the driest part of the year (July–September) to estimate vegetation health when the plants are most likely dependent on groundwater.

Annual Precipitation is the total precipitation for the water year (October 1st – September 30th) from the PRISM dataset. The amount of local precipitation can affect vegetation with more precipitation generally leading to higher NDVI and NDMI.

Depth to Groundwater measurements provide an indication of the groundwater levels and changes over time for the surrounding area. We used groundwater well measurements from nearby (<1km) wells to estimate the depth to groundwater below the GDE based on the average elevation of the GDE (using a digital elevation model) minus the measured groundwater surface elevation.

ICONOS Mapper Interconnected Surface Water in the Central Valley

ICONOS maps the likely presence of interconnected surface water (ISW) in the Central Valley using depth to groundwater data. Using data from 2011-2018, the ISW dataset represents the likely connection between surface water and groundwater for rivers and streams in California’s Central Valley. It includes information on the mean, maximum, and minimum depth to groundwater for each stream segment over the years with available data, as well as the likely presence of ISW based on the minimum depth to groundwater. The Nature Conservancy developed this database, with guidance and input from expert academics, consultants, and state agencies.

We developed this dataset using groundwater elevation data [available online](#) from the California Department of Water Resources (DWR). DWR only provides this data for the Central Valley. For GSAs outside of the valley, who have groundwater well measurements, we recommend following our methods to determine likely ISW in your region. The Nature Conservancy’s ISW dataset should be used as a first step in reviewing ISW and should be supplemented with local or more recent groundwater depth data.

Attachment C

Freshwater Species Located in the Vina Subbasin

To assist in identifying the beneficial users of surface water necessary to assess the undesirable result “depletion of interconnected surface waters”, Attachment C provides a list of freshwater species located in the Vina Subbasin. To produce the freshwater species list, we used ArcGIS to select features within the California Freshwater Species Database version 2.0.9 within the basin boundary. This database contains information on ~4,000 vertebrates, macroinvertebrates and vascular plants that depend on fresh water for at least one stage of their life cycle. The methods used to compile the California Freshwater Species Database can be found in Howard et al. 2015¹. The spatial database contains locality observations and/or distribution information from ~400 data sources. The database is housed in the California Department of Fish and Wildlife’s BIOS² as well as on The Nature Conservancy’s science website³.

Scientific Name	Common Name	Legal Protected Status		
		Federal	State	Other
BIRDS				
<i>Coccyzus americanus occidentalis</i>	Western Yellow-billed Cuckoo	Candidate - Threatened	Endangered	
<i>Riparia riparia</i>	Bank Swallow		Threatened

IDENTIFYING GDEs UNDER SGMA Best Practices for using the NC Dataset

The Sustainable Groundwater Management Act (SGMA) requires that groundwater dependent ecosystems (GDEs) be identified in Groundwater Sustainability Plans (GSPs). As a starting point, the Department of Water Resources (DWR) is providing the Natural Communities Commonly Associated with Groundwater Dataset (NC Dataset) online¹ to help Groundwater Sustainability Agencies (GSAs), consultants, and stakeholders identify GDEs within individual groundwater basins. To apply information from the NC Dataset to local areas, GSAs should combine it with the best available science on local hydrology, geology, and groundwater levels to verify whether polygons in the NC dataset are likely supported by groundwater in an aquifer (Figure 1)². This document highlights six best practices for using local groundwater data to confirm whether mapped features in the NC dataset are supported by groundwater.

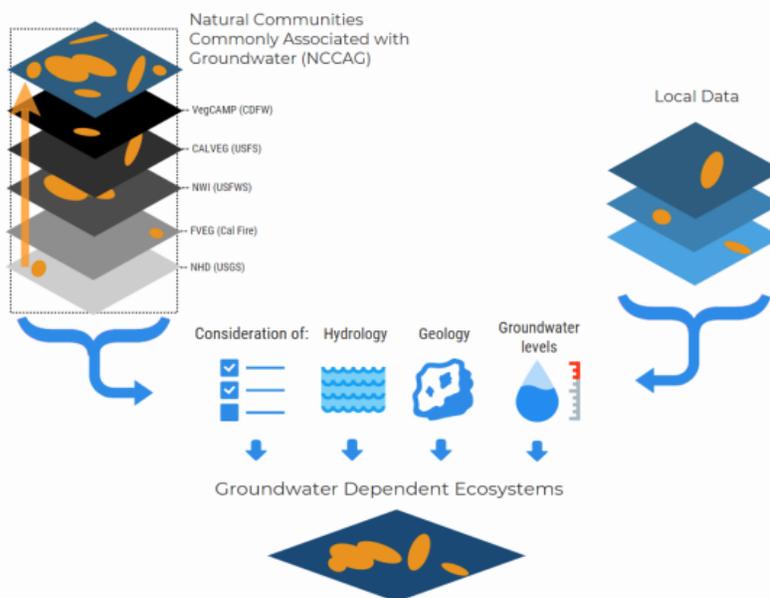

Figure 1. Considerations for GDE identification.
Source: DWR²

¹ NC Dataset Online Viewer: <https://gis.water.ca.gov/app/NCDataSetViewer/>

² California Department of Water Resources (DWR). 2018. Summary of the "Natural Communities Commonly Associated with Groundwater" Dataset and Online Web Viewer. Available at: <https://water.ca.gov/-/media/DWR-Website/Web-Pages/Programs/Groundwater-Management/Data-and-Tools/Files/Statewide-Reports/Natural-Communities-Dataset-Summary-Document.pdf>

The NC Dataset identifies vegetation and wetland features that are good indicators of a GDE. The dataset is comprised of 48 publicly available state and federal datasets that map vegetation, wetlands, springs, and seeps commonly associated with groundwater in California³. It was developed through a collaboration between DWR, the Department of Fish and Wildlife, and The Nature Conservancy (TNC). TNC has also provided detailed guidance on identifying GDEs from the NC dataset⁴ on the Groundwater Resource Hub⁵, a website dedicated to GDEs.

BEST PRACTICE #1. Establishing a Connection to Groundwater

Groundwater basins can be comprised of one continuous aquifer (Figure 2a) or multiple aquifers stacked on top of each other (Figure 2b). In unconfined aquifers (Figure 2a), using the depth-to-groundwater and the rooting depth of the vegetation is a reasonable method to infer groundwater dependence for GDEs. If groundwater is well below the rooting (and capillary) zone of the plants and any wetland features, the ecosystem is considered disconnected and groundwater management is not likely to affect the ecosystem (Figure 2d). However, it is important to consider local conditions (e.g., soil type, groundwater flow gradients, and aquifer parameters) and to review groundwater depth data from multiple seasons and water year types (wet and dry) because intermittent periods of high groundwater levels can replenish perched clay lenses that serve as the water source for GDEs (Figure 2c). Maintaining these natural groundwater fluctuations are important to sustaining GDE health.

Basins with a stacked series of aquifers (Figure 2b) may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage groundwater resources in shallow aquifers, such as perched aquifers, that support springs, surface water, domestic wells, and GDEs (Figure 2). This is because vertical groundwater gradients across aquifers may result in pumping from deeper aquifers to cause adverse impacts onto beneficial users reliant on shallow aquifers or interconnected surface water. The goal of SGMA is to sustainably manage groundwater resources for current and future social, economic, and environmental benefits. While groundwater pumping may not be currently occurring in a shallower aquifer, use of this water may become more appealing and economically viable in future years as pumping restrictions are placed on the deeper production aquifers in the basin to meet the sustainable yield and criteria. Thus, identifying GDEs in the basin should be done irrespective to the amount of current pumping occurring in a particular aquifer, so that future impacts on GDEs due to new production can be avoided. A good rule of thumb to follow is: *if groundwater can be pumped from a well - it's an aquifer.*

⁵ The Groundwater Resource Hub: www.GroundwaterResourceHub.org

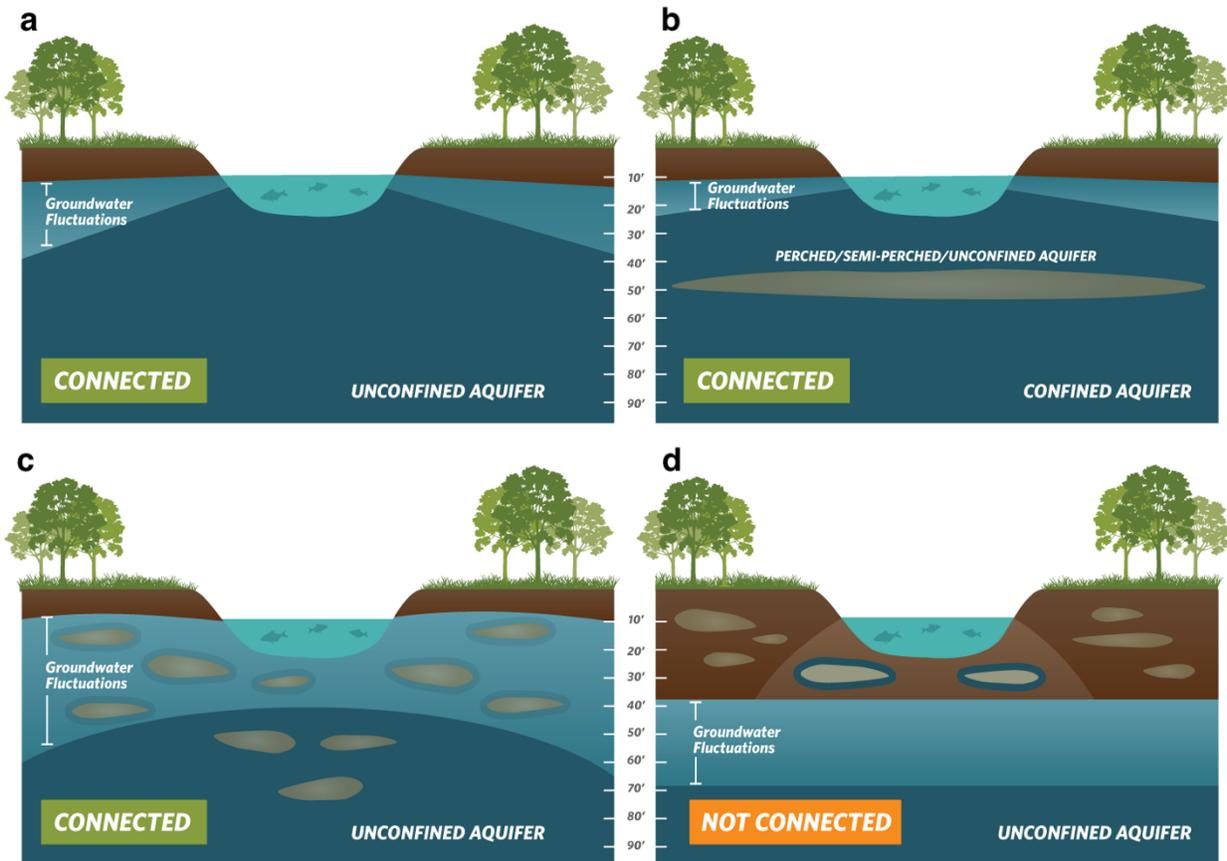

Figure 2. Confirming whether an ecosystem is connected to groundwater. Top: (a) Under the ecosystem is an unconfined aquifer with depth-to-groundwater fluctuating seasonally and interannually within 30 feet from land surface. **(b)** Depth-to-groundwater in the shallow aquifer is connected to overlying ecosystem. Pumping predominately occurs in the confined aquifer, but pumping is possible in the shallow aquifer. **Bottom: (c)** Depth-to-groundwater fluctuations are seasonally and interannually large, however, clay layers in the near surface prolong the ecosystem’s connection to groundwater. **(d)** Groundwater is disconnected from surface water, and any water in the vadose (unsaturated) zone is due to direct recharge from precipitation and indirect recharge under the surface water feature. These areas are not connected to groundwater and typically support species that do not require access to groundwater to survive.

BEST PRACTICE #2. Characterize Seasonal and Interannual Groundwater Conditions

SGMA requires GSAs to describe current and historical groundwater conditions when identifying GDEs [23 CCR §354.16(g)]. Relying solely on the SGMA benchmark date (January 1, 2015) or any other single point in time to characterize groundwater conditions (e.g., depth-to-groundwater) is inadequate because managing groundwater conditions with data from one time point fails to capture the seasonal and interannual variability typical of California’s climate. DWR’s Best Management Practices document on water budgets⁶ recommends using 10 years of water supply and water budget information to describe how historical conditions have impacted the operation of the basin within sustainable yield, implying that a baseline⁷ could be determined based on data between 2005 and 2015. Using this or a similar time period, depending on data availability, is recommended for determining the depth-to-groundwater.

GDEs depend on groundwater levels being close enough to the land surface to interconnect with surface water systems or plant rooting networks. The most practical approach⁸ for a GSA to assess whether polygons in the NC dataset are connected to groundwater is to rely on groundwater elevation data. As detailed in TNC’s GDE guidance document⁴, one of the key factors to consider when mapping GDEs is to contour depth-to-groundwater in the aquifer that is supporting the ecosystem (see Best Practice #5).

Groundwater levels fluctuate over time and space due to California’s Mediterranean climate (dry summers and wet winters), climate change (flood and drought years), and subsurface heterogeneity in the subsurface (Figure 3). Many of California’s GDEs have adapted to dealing with intermittent periods of water stress, however if these groundwater conditions are prolonged, adverse impacts to GDEs can result. While depth-to-groundwater levels within 30 feet⁴ of the land surface are generally accepted as being a proxy for confirming that polygons in the NC dataset are supported by groundwater, it is highly advised that fluctuations in the groundwater regime be characterized to understand the seasonal and interannual groundwater variability in GDEs. Utilizing groundwater data from one point in time can misrepresent groundwater levels required by GDEs, and inadvertently result in adverse impacts to the GDEs. Time series data on groundwater elevations and depths are available on the SGMA Data Viewer⁹. However, if insufficient data are available to describe groundwater conditions within or near polygons from the NC dataset, include those polygons in the GSP until data gaps are reconciled in the monitoring network (see Best Practice #6).

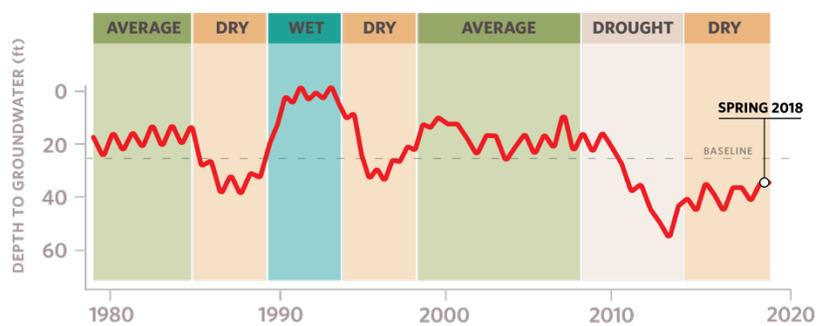

Figure 3. Example seasonality and interannual variability in depth-to-groundwater over time. Selecting one point in time, such as Spring 2018, to characterize groundwater conditions in GDEs fails to capture what groundwater conditions are necessary to maintain the ecosystem status into the future so adverse impacts are avoided.

⁶ DWR. 2016. Water Budget Best Management Practice. Available at:

https://water.ca.gov/LegacyFiles/groundwater/sqm/pdfs/BMP_Water_Budget_Final_2016-12-23.pdf

⁷ Baseline is defined under the GSP regulations as “historic information used to project future conditions for hydrology, water demand, and availability of surface water and to evaluate potential sustainable management practices of a basin.” [23 CCR §351(e)]

⁸ Groundwater reliance can also be confirmed via stable isotope analysis and geophysical surveys. For more information see The GDE Assessment Toolbox (Appendix IV, GDE Guidance Document for GSPs⁴).

⁹ SGMA Data Viewer: <https://sgma.water.ca.gov/webgis/?appid=SGMADataViewer>

BEST PRACTICE #3. Ecosystems Often Rely on Both Groundwater and Surface Water

GDEs are plants and animals that rely on groundwater for all or some of its water needs, and thus can be supported by multiple water sources. The presence of non-groundwater sources (e.g., surface water, soil moisture in the vadose zone, applied water, treated wastewater effluent, urban stormwater, irrigated return flow) within and around a GDE does not preclude the possibility that it is supported by groundwater, too. SGMA defines GDEs as "ecological communities and species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface" [23 CCR §351(m)]. Hence, depth-to-groundwater data should be used to identify whether NC polygons are supported by groundwater and should be considered GDEs. In addition, SGMA requires that significant and undesirable adverse impacts to beneficial users of surface water be avoided. Beneficial users of surface water include environmental users such as plants or animals¹⁰, which therefore must be considered when developing minimum thresholds for depletions of interconnected surface water.

GSAs are only responsible for impacts to GDEs resulting from groundwater conditions in the basin, so if adverse impacts to GDEs result from the diversion of applied water, treated wastewater, or irrigation return flow away from the GDE, then those impacts will be evaluated by other permitting requirements (e.g., CEQA) and may not be the responsibility of the GSA. However, if adverse impacts occur to the GDE due to changing groundwater conditions resulting from pumping or groundwater management activities, then the GSA would be responsible (Figure 4).

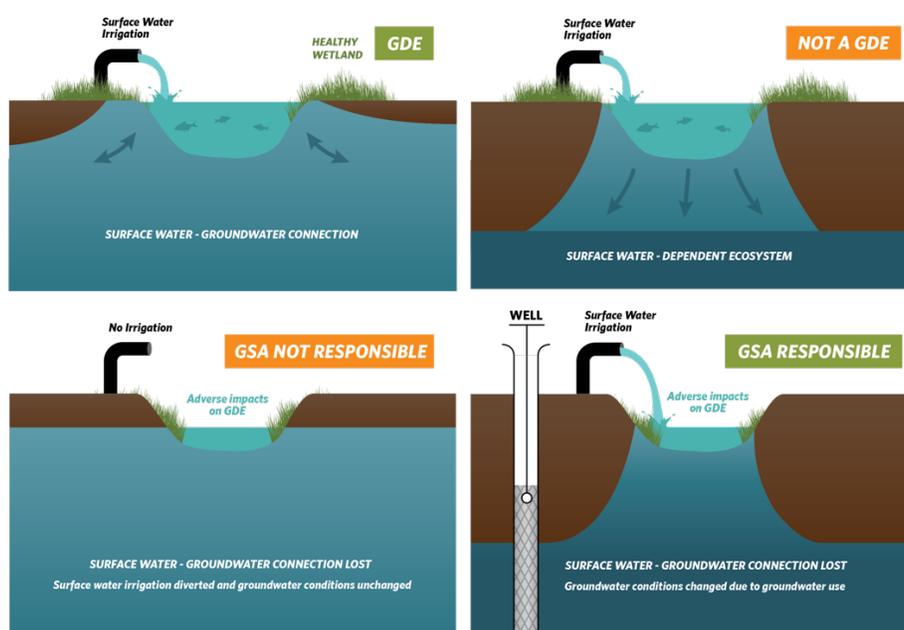

Figure 4. Ecosystems often depend on multiple sources of water. Top: (Left) Surface water and groundwater are interconnected, meaning that the GDE is supported by both groundwater and surface water. **(Right)** Ecosystems that are only reliant on non-groundwater sources are not groundwater-dependent. **Bottom: (Left)** An ecosystem that was once dependent on an interconnected surface water, but loses access to groundwater solely due to surface water diversions may not be the GSA's responsibility. **(Right)** Groundwater dependent ecosystems once dependent on an interconnected surface water system, but loses that access due to groundwater pumping is the GSA's responsibility.

¹⁰ For a list of environmental beneficial users of surface water by basin, visit: <https://groundwaterresourcehub.org/gde-tools/environmental-surface-water-beneficiaries/>

BEST PRACTICE #4. Select Representative Groundwater Wells

Identifying GDEs in a basin requires that groundwater conditions are characterized to confirm whether polygons in the NC dataset are supported by the underlying aquifer. To do this, proximate groundwater wells should be identified to characterize groundwater conditions (Figure 5). When selecting representative wells, it is particularly important to consider the subsurface heterogeneity around NC polygons, especially near surface water features where groundwater and surface water interactions occur around heterogeneous stratigraphic units or aquitards formed by fluvial deposits. The following selection criteria can help ensure groundwater levels are representative of conditions within the GDE area:

- Choose wells that are within 5 kilometers (3.1 miles) of each NC Dataset polygons because they are more likely to reflect the local conditions relevant to the ecosystem. If there are no wells within 5km of the center of a NC dataset polygon, then there is insufficient information to remove the polygon based on groundwater depth. Instead, it should be retained as a potential GDE until there are sufficient data to determine whether or not the NC Dataset polygon is supported by groundwater.
- Choose wells that are screened within the surficial unconfined aquifer and capable of measuring the true water table.
- Avoid relying on wells that have insufficient information on the screened well depth interval for excluding GDEs because they could be providing data on the wrong aquifer. This type of well data should not be used to remove any NC polygons.

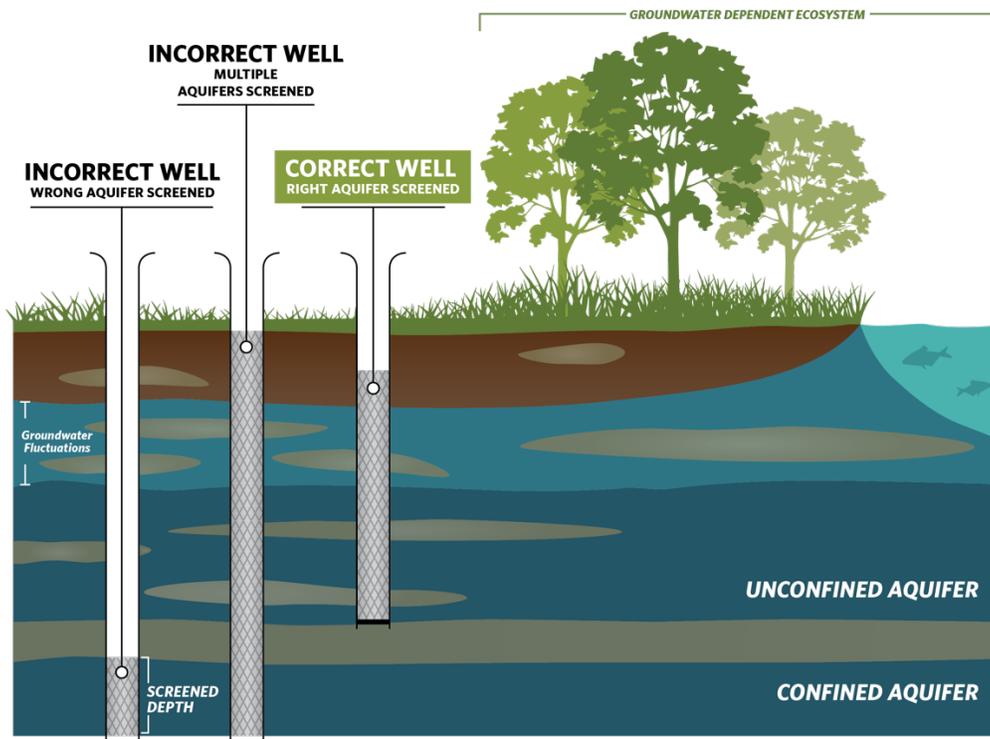

Figure 5. Selecting representative wells to characterize groundwater conditions near GDEs.

BEST PRACTICE #5. Contouring Groundwater Elevations

The common practice to contour depth-to-groundwater over a large area by interpolating measurements at monitoring wells is unsuitable for assessing whether an ecosystem is supported by groundwater. This practice causes errors when the land surface contains features like stream and wetland depressions because it assumes the land surface is constant across the landscape and depth-to-groundwater is constant below these low-lying areas (Figure 6a). A more accurate approach is to interpolate **groundwater elevations** at monitoring wells to get groundwater elevation contours across the landscape. This layer can then be subtracted from land surface elevations from a Digital Elevation Model (DEM)¹¹ to estimate depth-to-groundwater contours across the landscape (Figure b; Figure 7). This will provide a much more accurate contours of depth-to-groundwater along streams and other land surface depressions where GDEs are commonly found.

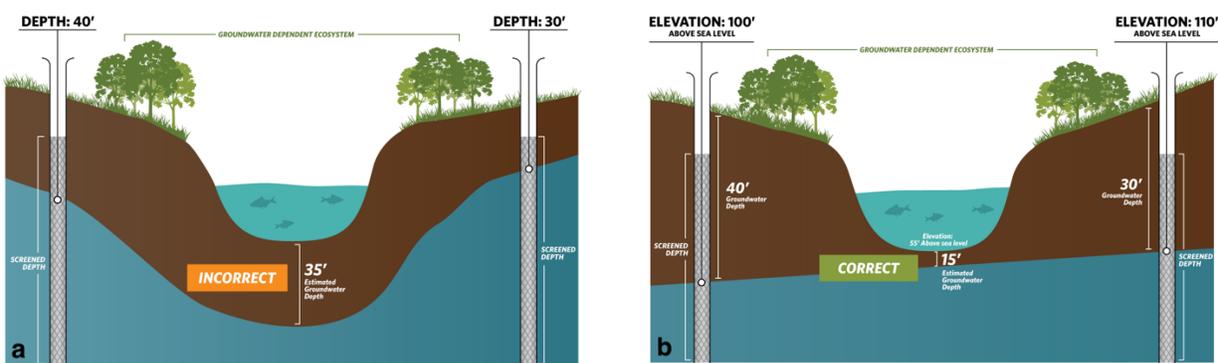

Figure 6. Contouring depth-to-groundwater around surface water features and GDEs. (a) Groundwater level interpolation using depth-to-groundwater data from monitoring wells. **(b)** Groundwater level interpolation using groundwater elevation data from monitoring wells and DEM data.

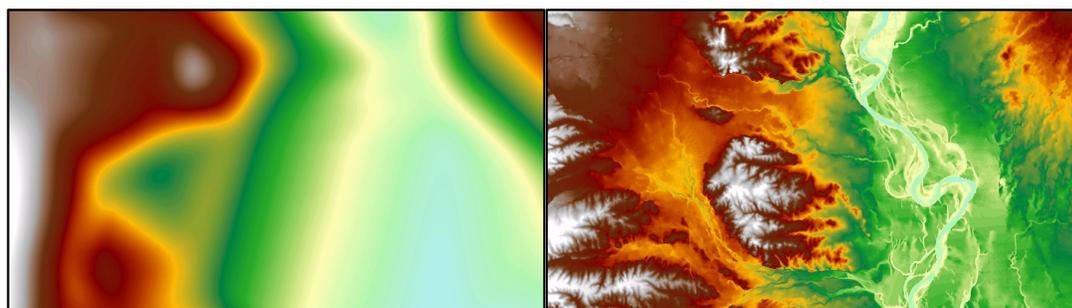

Figure 7. Depth-to-groundwater contours in Northern California. (Left) Contours were interpolated using depth-to-groundwater measurements determined at each well. **(Right)** Contours were determined by interpolating groundwater elevation measurements at each well and superimposing ground surface elevation from DEM spatial data to generate depth-to-groundwater contours. The image on the right shows a more accurate depth-to-groundwater estimate because it takes the local topography and elevation changes into account.

¹¹ USGS Digital Elevation Model data products are described at: <https://www.usgs.gov/core-science-systems/nep/3dep/about-3dep-products-services> and can be downloaded at: <https://iewer.nationalmap.gov/basic/>

BEST PRACTICE #6. Best Available Science

Adaptive management is embedded within SGMA and provides a process to work toward sustainability over time by beginning with the best available information to make initial decisions, monitoring the results of those decisions, and using the data collected through monitoring programs to revise decisions in the future. In many situations, the hydrologic connection of NC dataset polygons will not initially be clearly understood if site-specific groundwater monitoring data are not available. If sufficient data are not available in time for the 2020/2022 plan, **The Nature Conservancy strongly advises that questionable polygons from the NC dataset be included in the GSP until data gaps are reconciled in the monitoring network.** Erring on the side of caution will help minimize inadvertent impacts to GDEs as a result of groundwater use and management actions during SGMA implementation.

KEY DEFINITIONS

Groundwater basin is an aquifer or stacked series of aquifers with reasonably well-defined boundaries in a lateral direction, based on features that significantly impede groundwater flow, and a definable bottom. *23 CCR §341(g)(1)*

Groundwater dependent ecosystem (GDE) are ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface. *23 CCR §351(m)*

Interconnected surface water (ISW) surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted. *23 CCR §351(o)*

Principal aquifers are aquifers or aquifer systems that store, transmit, and yield significant or economic quantities of groundwater to wells, springs, or surface water systems. *23 CCR §351(aa)*

ABOUT US

The Nature Conservancy is a science-based nonprofit organization whose mission is *to conserve the lands and waters on which all life depends*. To support successful SGMA implementation that meets the future needs of people, the economy, and the environment, TNC has developed tools and resources (www.groundwaterresourcehub.org) intended to reduce costs, shorten timelines, and increase benefits for both people and nature.

Subject: COMMENTS ON THE VINA SUBBASIN DRAFT GROUNDWATER SUSTAINABILITY PLAN

The California Department of Fish and Wildlife's (Department) North Central Region is providing comments on the Vina Subbasin Draft Groundwater Sustainability Plan (GSP) prepared by the Vina Groundwater Sustainability Agency (GSA) and Rock Creek Reclamation District GSA pursuant to the Sustainable Groundwater Management Act (SGMA).

As trustee agency for the State's fish and wildlife resources, the Department has jurisdiction over the conservation, protection, and management of fish, wildlife, native plants, and the habitat necessary for biologically sustainable populations of such species (Fish & Game Code §§ 711.7 and 1802).

Development and implementation of GSPs under SGMA represents a new era of California groundwater management. The Department has an interest in the sustainable management of groundwater, as many sensitive ecosystems and species depend on groundwater and interconnected surface waters, including ecosystems on Department-owned and -managed lands within SGMA-regulated basins.

SGMA and its implementing regulations afford ecosystems and species specific statutory and regulatory consideration, including the following as pertinent to Groundwater Sustainability Plans:

- GSPs must **consider impacts to groundwater dependent ecosystems** (GDEs) (Water Code § 10727.4(l); see also 23 CCR § 354.16(g));
- GSPs must consider the interests of all beneficial uses and users of groundwater, including environmental users of groundwater (Water Code § 10723.2) and GSPs must **identify and consider potential effects on all beneficial uses and users of groundwater** (23 CCR §§ 354.10(a), 354.26(b)(3), 354.28(b)(4), 354.34(b)(2), and 354.34(f)(3));
- GSPs must **establish sustainable management criteria that avoid undesirable results** within 20 years of the applicable statutory deadline, including **depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water** (23 CCR § 354.22 *et seq.* and Water Code §§ 10721(x)(6) and 10727.2(b)) and describe monitoring networks that can identify adverse

Vina Subbasin
October 7, 2021
Page 2 of 13

impacts to beneficial uses of interconnected surface waters (23 CCR § 354.34(c)(6)(D)); and

- GSPs must **account for groundwater extraction for all water use sectors**, including managed wetlands, managed recharge, and native vegetation (23 CCR §§ 351(a) and 354.18(b)(3)).

Furthermore, the Public Trust Doctrine imposes a related but distinct obligation to consider how groundwater management affects public trust resources, including navigable surface waters and fisheries. Groundwater hydrologically connected to navigable surface waters and surface waters tributary to navigable surface waters are also subject to the Public Trust Doctrine to the extent that groundwater extractions or diversions affect or may affect public trust uses (*Environmental Law Foundation v. State Water Resources Control Board* (2018), 26 Cal. App. 5th 844). Accordingly, groundwater plans should consider potential impacts to and appropriate protections for navigable interconnected surface waters and their tributaries, and interconnected surface waters that support fisheries, including the level of groundwater contribution to those waters.

In the context of SGMA statutes and regulations, and Public Trust Doctrine considerations, the Department values SGMA groundwater planning that carefully considers and protects groundwater dependent ecosystems (GDEs) and fish and wildlife beneficial uses and users of groundwater and interconnected surface waters.

COMMENT OVERVIEW

The Department is writing to support ecosystem preservation in compliance with SGMA and its implementing regulations based on Department expertise and best available information and science.

The Department recognizes and appreciates the effort of the GSAs to characterize subbasin groundwater conditions based on the data available. However, the Department believes the GSP could improve its consideration of environmental users of groundwater and establish more protective management criteria. Accordingly, the Department recommends that Vina Subbasin GSAs address the following comments before submitting the GSP to the Department of Water Resources (DWR).

COMMENTS AND RECOMMENDATIONS

The Department comments are as follows:

- 1. Comment #1 Groundwater Dependent Ecosystems** (Groundwater Conditions, 2.2 Groundwater Dependent Ecosystems, starting page 67): GDE identification, required by 23 CCR § 354.16(g), is based on methods that risk exclusion of ecosystems that may depend on groundwater.

a. *Issues:*

- i. “Not Likely a GDE” Area Identification: The methodology used to classify potential GDE areas within the Natural Communities Commonly Associated with Groundwater (NCCAG) dataset primarily involved desktop review of aerial imagery from four drought years: 2007, 2009, 2013, and 2015 (line 2515). Potential GDE areas were classified as “Not Likely a GDE” if the areas were located within 150 feet of perennial surface water supplies, 150 feet of rice fields, 50 feet of other irrigated agriculture, or 150 feet of agricultural-dependent surface waters. This GDE-elimination method may disregard a GDE’s adaptability and opportunistic approach to accessing water in which the vegetation may rely on *both* surface water and groundwater between seasons and years. Without additional analysis that compares the potential rooting depths of groundwater dependent vegetation with the depth to groundwater below the ground surface, there is insufficient information to categorize these potential GDE areas as “Not Likely a GDE.” The GDE analysis also classifies potential GDEs from the NCCAG dataset as “Not Likely a GDE” if the vegetation “did not indicate surviving conditions” over the four drought years reviewed for the analysis. During drought years, it is likely that GDEs were experiencing adverse impacts due to combined groundwater depletion and reduced surface water availability. For instance, in 2015, groundwater extraction increased to replace more than 70% of lost agricultural water supplies (Lund 2018); additional groundwater pumping during drought years may have lowered the groundwater table below the rooting zone of GDEs that had previously been able to access groundwater, leading to significant impacts or mortality. The GSP states that impacts or minimum threshold exceedances that occur during dry water year types would not constitute an undesirable result (See Comment #2(iv)). It is inappropriate to simultaneously abdicate management responsibility for impacts to groundwater users during dry water year types (see Comment #2(iv)) while at the same time relying on impacts that occurred during drought years to categorize potential GDE areas as “Not Likely a GDE.”
- ii. Special Status Species: SGMA defines GDEs as ecological communities *or species* that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface [23 CCR § 351 (m)]. The GSP does not identify or discuss species that may be present within the

subbasin that rely on groundwater, groundwater dependent ecosystems, or interconnected surface waters.

- iii. Tree Species: In discussing potential impacts of groundwater depletions on GDEs or interconnected surface waters, the GSP refers to “deep-rooted tree species” (lines 189, 3406, 3698). This phrasing is narrow and excludes consideration of all vegetation types that may be groundwater dependent or supported by interconnected surface waters apart from tree species.

b. *Recommendations*:

- i. “Not Likely a GDE” Area Identification: To assess potential GDE areas located near surface waters or irrigated areas, the GSP should incorporate a comparison of potential rooting depths with the groundwater surface elevation. Analysis of groundwater surface elevations should include multiple years that are representative of multiple water year types. The GDE analysis as it relates to survivability during drought years should consider the impacts of drought and increased pumping on groundwater elevation and compare those levels to GDE rooting depths. A more robust analysis would also incorporate other metrics of GDE health, including Normalized Difference Vegetation Index (NDVI) to compare between potential GDE areas and known non-groundwater dependent vegetation, rather than simply reviewing aerial imagery for indications of survival. Until sufficient information is presented to support the classification of these areas as “Not Likely a GDE,” the areas should be conservatively classified as “Uncertain.” The Department appreciates the GSP’s acknowledgement that Valley Oak (*Q. lobata*) can access groundwater at a variety of depths and inclusion of areas containing Valley Oak communities as “Likely GDE.”
- ii. Special Status Species: The Department recommends the GSP include a list of special status species that may be present within the Vina Subbasin and an assessment of each species’ likely groundwater dependence. The GSP should also include a spatial assessment of special status species within the subbasin to characterize which surface waters or GDE areas provide these species habitat or forage; this level of GDE-species-relationship assessment enables GSAs to prioritize GDE monitoring and management decisions.
- iii. Tree Species: The Department recommends the GSP language referring to “deep-rooted tree species” be updated to be inclusive of groundwater dependent vegetation more broadly.

2. Comment #2 Sustainable Management Criteria (Sustainable Management Criteria; 3.3 Groundwater Levels Sustainable Management Criteria, 3.8 Interconnected Surface Water Sustainable Management Criteria): Interconnected surface water (ISW) sustainable management criteria (SMC) is unlikely to protect against undesirable results for groundwater dependent ecosystems and fish and wildlife beneficial uses and users of groundwater and interconnected surface waters.

a. *Issues:*

- i. Groundwater Level Proxy Metric: The GSP identifies a data gap related to interconnected surface waters within the subbasin and therefore defaults to using groundwater levels as a proxy metric. However, the GSP does not provide evidence that “significant correlation exists between groundwater level elevations” and depletions of interconnected surface waters [23 CCR § 354.36(b)(1)]. In its discussion of available monitoring data from nested or multi-completion wells within the subbasin, the GSP identifies well 23N01W31M, located adjacent to the Sacramento River (page 47, line 1947). The GSP indicates that the shallowest of the 4 nested wells, screened from 65 to 75 feet below ground surface (bgs), is likely in direct continuity with river levels, while the deeper three wells display greater fluctuation and generally track one another, indicating less direct continuity with the river. While the Department recognizes the lack of available data and uncertainty surrounding aquifer heterogeneity as it relates to vertical conductivity between aquifer zones, if a significant correlation is lacking between the shallower aquifer zones that are likely interconnected with surface waters and deeper zones where pumping occurs and that are monitored for the groundwater level sustainable management criteria (SMCs), use of groundwater levels as a proxy metric for ISW depletions may misinform groundwater management activities and poorly predict instream habitat conditions for fish and wildlife species.
- ii. ISW Framework: The Department acknowledges the GSP’s identification of the data gap related to interconnected surface water and appreciates the development of a framework to guide data collection efforts. However, while the ISW Framework identifies the types of measurements and data necessary to better characterize groundwater-surface water interactions within the subbasin, it does not discuss the methods that will be used to identify the number or locations of groundwater monitoring wells or stream gages.

- iii. Minimum Thresholds and Measurable Objectives: Minimum thresholds (MTs) and measurable objectives (MOs) for groundwater levels, and by proxy for depletions of interconnected surface water, are not likely to prevent undesirable results for environmental beneficial uses and users of groundwater and interconnected surface water, including groundwater dependent ecosystems. For representative monitoring sites, measurable objectives are set to the groundwater level projected to occur in 2030 based on the trendline of historical data; management to this level would result in groundwater levels falling below historic lows for many of the monitoring wells. The GSP states that the year 2030 was chosen due to the assumption that it would take until this date to implement projects and management actions (line 3490). While the Department acknowledges that some planned PMAs involving supply augmentation may require this length of time to implement, other projects or management actions related to conservation could be implemented in a shorter timeframe, allowing the GSAs to establish more protective MOs rather than defaulting to the trend of long-term groundwater decline, which SGMA was designed to combat. MTs for groundwater levels, which the GSP asserts are designed to be protective of domestic wells, are set far below MOs, and would allow groundwater levels to fall significantly before experiencing what the GSP considers an undesirable result. For instance, within the Vina North Management Area, the MT for representative monitoring site 25C001M is set 80 feet below the MO (Table 3-1, page 107). In setting groundwater level SMCs as proxy metrics for the depletion of interconnected surface waters, the GSP fails to analyze or discuss potential impacts of the established criteria on the rate or volume of surface water depletions or on groundwater dependent ecosystems in areas that have historically demonstrated shallow groundwater levels accessible to environmental users. Under the established SMCs that allow for continued groundwater decline from current conditions, the Department expects that fish and wildlife beneficial uses and users of groundwater and interconnected surface waters could lose access to shallow groundwater water supplies and experience significant and unreasonable impacts prior to the minimum thresholds being reached, including decline of GDEs and ISW habitat suitable for cold water fisheries. The established SMCs would allow groundwater levels to drop well below levels that occurred in 2015, which was the second of back-to-back critically dry water years in the

Sacramento Valley during which time vegetated and aquatic GDEs experienced adverse impacts including stressed or dying riparian vegetation, poor instream habitat availability, and increased water temperatures (DFW 2019). The Department does not believe groundwater levels above the proposed minimum thresholds and below the proposed measurable objectives (in the margin of operational flexibility) will allow the basin to achieve sustainability, particularly with respect to avoiding undesirable results for fish and wildlife beneficial uses and users of groundwater and interconnected surface water.

- iv. Undesirable Results: The GSP defines an undesirable result for depletions of interconnected surface waters as “avoiding significant and unreasonable depletion of surface water flows caused by groundwater pumping that significantly impacts beneficial uses.” Though the GSP includes a list of potential impacts to environmental uses and users as identified by stakeholders (page 113, line 3692), the GSP does not include any discussion or analysis of whether the established SMCs sufficiently avoid these identified potential impacts to GDEs or environmental users of interconnected surface waters. Additionally, the GSP notes that groundwater levels that fall below the minimum threshold during hydrologically dry or critically dry years are not considered to be an indicator of undesirable results (page 104, line 3424). This means proposed indicators of undesirable results (i.e., SMC) for groundwater levels and depletions of interconnected surface water effectively do not exist for dry water years. This absence of undesirable results indicators for certain water years means beneficial users of groundwater and interconnected surface water may experience significant and unreasonable effects throughout the duration of dry or critical water years before the undesirable results are ‘identified’ and managed. Accordingly, there is no groundwater management accountability during the most challenging of years for water resource managers and fish and wildlife beneficial users alike. Moreover, the frequency and intensity of dry water year types is expected to increase in California (Mann & Gleick, 2015), meaning if accepted as is, this GSP would have no groundwater management accountability during increasingly prevalent and challenging periods of dryness without the certainty of subsequent wet periods.
- v. SMC Triggers: The GSP states that for the established SMCs, if observed data “trend toward the locally defined MT, this will trigger action on part of the GSAs.” It is unclear over what time period data will need to be

collected in order to establish a 'trend' toward the SMCs, and what action will be triggered.

b. *Recommendations:*

- i. Groundwater Level Proxy Metric: To justify use of groundwater elevations as a proxy metric for depletions of interconnected surface water until additional data can be collected, the GSP should specify how groundwater elevations are significantly correlated to surface water depletions. Alternatively, if groundwater elevation is not a defensible proxy, the GSP should: 1) specify their plans for better approximating the volume and timing of ISW depletions attributable to groundwater extraction [23 CCR § 354.28(c)(1)] using the anticipated data collection that will fill the ISW data gap (See Comment #5); and 2) select more conservative interim SMC to protect ISW until such time as more information is available.
- ii. ISW Framework: The Department recommends that the GSP identify discrete timing and locations for planned groundwater and streamflow monitoring sites as needed to address the identified ISW data gap. Installation of wells and gages and data collection should be completed prior to the first 5-year plan update (See Comment #5).
- iii. Minimum Thresholds and Measurable Objectives: The Department recommends the GSP identify representative monitoring sites located near interconnected surface waters and/or groundwater dependent ecosystems and reselect minimum thresholds that would better protect environmental uses and users of groundwater, rather than enabling immense declines in groundwater over the implementation horizon.
- iv. Undesirable Results: The Department recommends that the GSP include additional information related to how environmental beneficial users of groundwater may experience the effects of undesirable results. For instance, the GSP should explicitly discuss the relationship between the proxy groundwater level SMCs, modeled monthly depletions of interconnected surface waters, water temperatures, and the impacts of lowering groundwater levels below historic lows on groundwater dependent ecosystems. The GSP should also identify undesirable results indicators for dry and critically dry water years for all sustainability indicators.
- v. SMC Triggers: While the Department appreciates that the GSP includes discussion of triggers that will initiate GSA action to avoid reaching minimum thresholds, the Department recommends establishing specific

trigger metrics for each sustainability indicator that when reached, would initiate GSA action, and defining the actions to be taken. For environmental users of groundwater, including groundwater dependent ecosystems, triggers should include not only groundwater levels but also physical indicators such as NDVI.

- 3. Comment #3 Monitoring Network** (Monitoring Networks, 4.9.1 Groundwater Levels, 4.10 Network Assessments and Improvements): The groundwater level monitoring network may not sufficiently monitor impacts to groundwater dependent ecosystems.

 - a. *Issue*: The GSP uses both the groundwater level SMCs and representative monitoring network as a proxy for evaluating impacts to interconnected surface waters and GDEs until additional information can be collected. The GSP primarily considered domestic well protection when establishing SMCs for groundwater levels and selecting representative monitoring sites. It is unclear whether any of the selected groundwater level monitoring wells are located near areas with likely groundwater dependent ecosystems and if plan implementation will involve comparing water depths in representative monitoring sites to the rooting depths of nearby GDE communities.
 - b. *Recommendation*: The Department recommends that the GSP assess the groundwater level monitoring network, and by proxy, the monitoring network for interconnected surface waters, for its ability to characterize potential impacts and undesirable results for groundwater dependent ecosystems (See Comment 2(iv)). If wells within the representative monitoring network are not located near identified groundwater dependent ecosystems, a discrete number of groundwater monitoring wells should be installed to capture groundwater trends that would affect priority GDEs. Additional analysis related to the locations of special status species within the subbasin and the groundwater dependent ecosystems that support them can be used to prioritize areas for increased monitoring (See Comment 1(ii)).

- 4. Comment #4 Project and Management Actions** (Project and Management Actions; 5.2.2 Project Implementation; starting page 138): Project and management actions (PMAs) may not be sufficient to achieve sustainability, and timelines for pursuing additional PMAs are needed.

 - a. *Issue*: The Department recognizes that the GSP identifies Potential Projects that are in the planning phase and may be implemented in addition to the four Planned Projects if necessary to achieve sustainability in the subbasin. However, the GSP fails to identify specific metrics or timelines that would trigger the

implementation of additional PMAs. The Streamflow Augmentation project (5.2.3.3, page 144) relies on excess surface water being made available from the Upper Watershed and would involve potentially lengthy permitting and regulatory review to change water rights as necessary. The GSP states that this project is expected to reduce groundwater demand by 1,000 to 5,000 acre-feet per year, or up to half of the projected 10,000 acre-foot per year overdraft within the subbasin. Should unexpected delays occur, or if sufficient surface water is unavailable in the Upper Watershed, additional PMAs will be necessary.

- b. *Recommendation:* The GSP should include details on specific metrics, targets, and timelines that if not reached with implementation of the planned PMAs will trigger the implementation of additional PMAs. The Department recommends identifying the projects, including those aimed at reducing demand through conservation, that could be implemented on shorter timescales if needed for the subbasin to achieve sustainability.

5. Comment # 5 Interconnected Surface Water Data Gap (Plan Implementation; 6.3 Schedule for Implementation; starting page 167): A more detailed time schedule for collecting additional data and revising the sustainable management criteria for depletion of interconnected surface water is needed.

- a. *Issue:* The GSP identifies information related to the depletion of interconnected surface water as a data gap, and the plan proposes a framework to collect additional information needed to revise the ISW SMCs. The GSP states that “an aggressive schedule” has been provided to fill the data gap in Section 6. However, the only time schedule related to filling identified data gaps identified during Department review is in Figure 6-1, which displays an “Interconnected Stream Monitoring” Data Gap filling effort start date of February 1, 2022, and an end date of April 1, 2042. No discrete time schedule is provided for installation of necessary groundwater wells and stream gages, refinement of the characterization of interconnected surface waters within the subbasin, and updates to the SMCs.
- b. *Recommendation:* The GSP should include a detailed time schedule for completing each action as outlined in the ISW SMC Framework to characterize interconnected surface waters in the subbasin and establish appropriate SMCs. The ISW SMC Framework should be completed prior to the first 5-year plan update so that management criteria can be effectively established to protect environmental users of groundwater and interconnected surface waters throughout the implementation period.

CONCLUSION

In conclusion, though the draft GSP accurately identifies the need to improve monitoring of shallow groundwater and interconnected surface water systems, the GSP lacks a robust analysis of potential impacts to environmental beneficial users and should establish more protective management criteria. The Department recommends that the Vina Subbasin GSAs address the above comments before GSP submission to DWR to best prepare for the following regulatory criteria for plan evaluation:

1. The assumptions, criteria, findings, and objectives, including the sustainability goal, undesirable results, minimum thresholds, measurable objectives, and interim milestones are not reasonable and/or not supported by the best available information and best available science. [23 CCR § 355.4(b)(1)] (See Comments #1, 2, 3)
2. The GSP does not identify reasonable measures and schedules to eliminate data gaps. [23 CCR § 355.4(b)(2)] (See Comments #3, 5)
3. The interests of the beneficial uses and users of groundwater in the basin, and the land uses and property interests potentially affected by the use of groundwater in the basin, have not been considered. [23 CCR § 355.4(b)(4)] (See Comments #1, 2, 3)
4. The projects and management actions are not feasible and/or not likely to prevent undesirable results and ensure that the basin is operated within its sustainable yield. [23 CCR § 355.4(b)(5)] (See Comment #4)

The Department appreciates the opportunity to provide comments on the Vina Subbasin Draft GSP. Please contact Bridget Gibbons, Environmental Scientist, by email at Bridget.Gibbons@wildlife.ca.gov with any questions.

Sincerely,

DocuSigned by:

Re: Comments to Draft Groundwater Sustainability Plan

Dear Board Members:

The purpose of this letter is to provide Vina Groundwater Sustainability Agency (Vina GSA) and Rock Creek Reclamation District Groundwater Sustainability Agency (Rock Creek GSA), collectively the “GSAs,” with the comments of the Agricultural Groundwater Users of Butte County (AGUBC) to the GSAs’ draft groundwater sustainability plan (GSP). In addition, this letter reiterates some of the past comments AGUBC submitted to the GSAs that remain unresolved.

First and foremost, we appreciate the dedication and hard work by the GSAs’ management staff and Ad Hoc Committees, as well as their consultants, in putting together this draft GSP. Further, we appreciate the previous opportunities to comment on individual draft chapters of the GSP as they were developed, as well as this opportunity to comment on the comprehensive draft GSP. It is clear that the GSAs have taken past comments into consideration. We hope the following comments are constructive and will likewise be considered in finalizing the draft GSP for submission to the Department of Water Resources (DWR). In considering the following comments, we recognize that this draft GSP is a “living” document and will undergo updates and modifications as more information is gathered to help the Vina Subbasin reach sustainability by 2042 and beyond.

Provided are our specific comments:

1. We support the overall approach for Minimum Thresholds (MT) and Measurable Objectives (MO) for the Chronic Lowering of Groundwater Levels.

The polygon approach to define areas related to the selected representative monitoring sites (RMS) helps to avoid overlap of information and tie in land and aquifer characteristics with the RMS. We anticipate that this polygon approach may be further refined with more information. Further, the MTs and MOs that have been established for the Vina North and Vina South management areas provide sufficient operating flexibility to help the landowners realistically achieve the goal of the MOs and protect sustainably constructed domestic wells, while allowing for flexibility to weather the next 20 years as we endeavor together to reach sustainability. Consequently, we concur with the approach taken in establishing the Sustainable Management Criteria (SMC) for chronic lowering of groundwater levels and encourage continued application of the methodologies expressed in the draft GSP for all management areas.

2. The draft GSP contains numerous data gaps affecting future GSP implementation.

While we appreciate the time and effort the GSAs have committed to preparing this draft GSP, there are still numerous data gaps that must be addressed, which is acknowledged in several places in the draft GSP. Moreover, some of these data gaps exist in crucial areas of the draft GSP. For example, Section 3.8 of the SMC chapter regarding the Interconnected Surface Water SMC lacks: (1) the “definition of stream reaches and associated priority habitat;” (2) “streamflow measurements to develop profiles at multiple time periods;” and (3) “measurements of groundwater levels directly adjacent to stream channels, first water bearing aquifer zone, and deeper aquifer zones.” (Pg. 113; Lines 3707 – 3711.) This one section alone is missing three crucial points of information that will likely dramatically change this SMC once developed. Furthermore, the draft GSP acknowledges in the SMC chapter that additional data regarding domestic well information will be needed to refine the data set in monitoring the chronic lowering of groundwater levels criteria. (Pg. 104; Lines 3445 – 3454.) These are just two examples of the data gaps contained (and acknowledged) throughout the draft GSP.

We look forward to the GSAs addressing and filling in the data gaps throughout the draft GSP and request that the GSAs provide ample opportunity for stakeholders to engage with the GSAs as they address these data gaps and revise the GSP in the coming years. Such engagement should not be limited to discussions with the Vina Stakeholder Advisory Committee (Vina SHAC) but should involve workshops and targeted discussions with stakeholder groups, where

applicable (such as the Butte County Farm Bureau and the AGUBC), to get important feedback. To that end, the draft GSP should be revised to reflect that commitment.

3. The draft GSP should provide additional clarity regarding how groundwater allocations will be imposed, if at all.

We thank the GSAs for including a public review component as part of the groundwater allocation implementation process. While we understand that implementation of groundwater allocations is a “last resort” (Pg. 160, Line 4992), we believe that public participation will be a crucial component of this management action, should it ever be explored.

Currently, Section 5.3.7 of the Projects and Management Actions chapter regarding Groundwater Allocations provides, in relevant part, that “[t]he implementation of [groundwater allocations] would be based on an evaluation by the Joint Management Committee (see Appendix X).” (Pg. 160, Lines 4995 – 4996.) This section then goes on to provide that “the GSAs will consider [groundwater allocations] through a public process ultimately decided by the GSA Boards.” (Pg. 160, Lines 5002 – 5004.)

While we are supportive of this process, we note that the draft GSP does not include an “Appendix X.” We assume that “Appendix X” was meant as a placeholder until the GSAs knew exactly which appendix number would be used for the coordination agreement between the two GSAs. We request that the GSAs confirm whether this assumption is correct, and, if so, that the GSAs revise the draft GSP to reflect the correct appendix number. If, however, this assumption is not correct, then we are left unsure as to the contents of this document. And to the extent that “Appendix X” describes the factors the Joint Management Committee will evaluate in making its determination regarding this management action and how the Joint Management Committee will weigh those evaluations, we request that the GSAs include that information in the draft GSP.

4. The draft GSP should remove its use of the phrase “suitable habitat.”

In our August 23, 2021 letter, we brought to the GSAs’ attention its use of the undefined phrase “suitable habitat.” In that letter, we requested that the GSAs remove this phrase and instead reflect the language used in other GSPs that DWR has already approved. In response to that letter, the GSAs removed this phrase from Section 3.4 of the SMC chapter regarding the Groundwater Storage SMC. While we appreciate that revision, we believe additional language is necessary to provide clarity regarding the scope of the term “environmental uses.” To alleviate this concern, we recommend that the GSAs revise Section 3.4 to provide as follows:

Revised Section 3.4

“Sustained groundwater storage volumes are insufficient to support rural areas and communities, the agricultural economic base of the region, and environmental uses *of groundwater.*”

Further, the phrase “suitable habitat” is still used in two other sections of the draft GSP. In describing the emphasis of management objectives for SMCs, Section 3.1 provides that:

“Sustainable management criteria within the Vina Subbasin emphasize management objectives related to domestic, municipal, and agricultural wells as well as *suitable habitat.*”

(Pg. 101; Lines 3333 – 3335; emphasis added.)

Additionally, Section 3.5 of the SMC chapter regarding the Water Quality SMC still relies on this phrase in describing undesirable results. Specifically, Section 3.5.1 provides, in relevant part, that an undesirable result coming from degraded water quality is experienced if:

“Groundwater pumping compromises the long-term viability of rural areas and small communities, the agricultural economic base of the region, and environmental uses for *suitable habitat. . . .*”

(Pg. 108, Lines 3556 – 3558; emphasis added.)

We again request that the GSAs remove the phrase “suitable habitat” from both Sections 3.1 and 3.5.1. As an alternative, we recommend that the GSAs revise these two sections to reflect the recommended revision to Section 3.4:

Revised Section 3.1

“Sustainable management criteria within the Vina Subbasin emphasize management objectives related to domestic, municipal, and agricultural wells as well as *environmental uses of groundwater.*”

Revised Section 3.5.1

“Groundwater pumping compromises the long-term viability of rural areas and small communities, the agricultural economic base of the region, and *environmental uses of groundwater.*”

While not a perfect resolution, we believe these recommended revisions would help focus the issue and allow for further discussion as data gaps are filled and monitoring conducted as described in the draft GSP.

5. There are some portions of the draft GSP that require further clarification and/or modification to avoid confusion.

Finally, there are several additional areas of the draft GSP that require further clarification and/or modification. Attached is a “comment tracking sheet,” as provided by the GSAs, detailing these requests for clarification and/or modification. Of these comments, we believe the two following comments deserve highlight:

- (i) Comment Regarding Chapter 2, Lines 3212 – 3225; and
- (ii) Comment Regarding Chapter 5, Lines 4477 0 4506.

Thank you for the opportunity to provide these comments. We appreciate the significance of the considerations and decisions the GSAs must undertake, and we look forward to working with you further regarding these matters.

Very truly yours,

Richard McGowan,

On behalf of the AGUBC Board of
Directors

Sent via email to: VinaGSA@gmail.com

Re: Comments on the Draft Groundwater Sustainability Plan for the Vina Groundwater Sustainability Agency

To Vina Subbasin Groundwater Sustainability Agencies,

Audubon California appreciates the opportunity to provide public comment on the draft Groundwater Sustainability Plan (GSP) for the Vina Subbasin. Audubon California is a statewide nonprofit organization with a mission to protect birds and the places they need. Our organization has a long history of solutions-focused work in the Central Valley in collaboration with state and federal agencies, water districts, non-profits, and landowners. Audubon is reviewing draft GSPs as a stakeholder for the environment with a particular focus on managed wetlands. We are commenting on draft GSPs to provide technical assistance to Groundwater Sustainability Agencies (GSAs) to improve their GSPs prior to their final submission to the Department of Water Resources in January 2022. Audubon would also like to identify areas of opportunity to partner with landowners and GSAs to provide groundwater and wildlife habitat benefits in the implementation of the Sustainable Groundwater Management Act (SGMA).

Over 90 percent of historic wetlands in the Central Valley have been replaced with agriculture or urban development. Disconnected from natural water sources as a consequence of surface water diversions and groundwater over-pumping, wetland landowners must utilize surface water deliveries or pump groundwater to provide flooded habitat. But managed wetlands provide outsized public trust benefits for their minor water use.

The remaining wetlands in the Central Valley are a critical component of the Pacific Flyway, supporting millions of migratory waterfowl, hundreds of thousands of shorebirds, and state listed species like the Tricolored Blackbird. Central Valley managed wetlands are part of California's commitment to national and international Pacific Flyway agreements and provide significant public trust benefits, including habitat for migratory birds, recharge of overdrafted aquifers, carbon sequestration, and recreation opportunities for birders, hunters, and disadvantaged communities.

Managed wetlands require specific consideration in GSPs under SGMA statute and regulations, as detailed below. GSAs are required to identify managed wetlands as beneficial users of groundwater and as land uses and property interests and should recognize this land use consistent with other active users of surface and groundwater. The overall basin water budget must include managed wetlands as a specific water use sector and the GSP is required to consider the effects of the GSP on managed wetlands as a beneficial user or land use.

When GSPs fail to adequately consider the water needs and recharge contributions of managed wetlands, projects and management actions may ignore managed wetlands, their need for protection as public trust resources, and their potential to be part of sustainability solutions. If future actions include groundwater allocations, managed wetlands face the potential of being excluded if not recognized in the GSP, risking further loss in critical wetland acreage.

SGMA Requirements Related to Managed Wetlands

A primary requirement for GSAs during GSP development is the consideration of the interests of “all beneficial uses and users of groundwater” [Water Code Section 10723.2], which includes “[e]nvironmental users of groundwater” [Water Code Section 10723.2(e)].

Articulated into the SGMA regulations, the concept of beneficial uses and users of groundwater is first represented in CCR, Title 23, Section 354.10. Notice and Communication, which directs the GSP to “...include a summary of information relating to notification and communication by the Agency with other agencies and interested parties including the following: (a) A description of the beneficial uses and users of groundwater in the basin, including the land uses and property interests potentially affected by the use of groundwater in the basin, the types of parties representing those interests, and the nature of consultation with those parties.” [emphasis added].

Furthermore, the SGMA regulations provide a definition that explicitly includes managed wetlands as a beneficial user where:

“‘Water use sector’ refers to categories of water demand based on the general land uses to which the water is applied, including urban, industrial, agricultural, managed wetlands, managed recharge, and native vegetation.” CCR, Title 23, Section 351(al) [emphasis added].

GSAs are then directed to include all water user sectors in the description of the GSP area and to quantify groundwater use by these sectors in the historic, current and projected budgets [emphasis added]:

CCR §354.8. Description of Plan Area: Each Plan shall include a description of the geographic areas covered, including the following information:

- (a) One or more maps of the basin that depict the following, as applicable:
 - (4) Existing land use designations and the identification of water use sector and water source type.

and,

CCR §354.18. Water Budget:

- (b) The water budget shall quantify the following, either through direct measurements or estimates based on data:
 - (3) Outflows from the groundwater system by water use sector, including evapotranspiration, groundwater extraction, groundwater discharge to surface water sources, and subsurface groundwater outflow.

Given these explicit requirements, GSAs are required to identify and map managed wetlands and include their water needs in water budgets in the GSP.

Furthermore, each GSP is also required to describe “undesirable results” where such included:

“Potential effects on the beneficial uses and users of groundwater, on land uses and property interests, and other potential effects that may occur or are occurring from undesirable results.” CCR, Title 23, Section 354.26(b)(3) [emphasis added]

Comment Overview

GSAs are required to consider public trust resources in their GSPs, including managed wetlands. In reviewing the Vina Subbasin draft GSP, we see VGSA is working hard to minimize the impacts to it growers in the subbasin. It is essential these efforts also include the managed wetlands. As beneficial users of water these habitats provide essential waterbird food and critical habitat, often requiring the application of surface or groundwater similar to cropped lands.

While the Butte Basin Groundwater Model (BBGM) used to prepare historic, current and future water budgets includes reference to managed wetlands acreage and demand (a draft version of the BBGM model documentation, as provided in October 2021, was reviewed), the resulting representation in the GSP is limited and leads to confusion regarding the future of managed wetlands in the Vina Subbasin. This is most prominently represented in *Table 2-7: Water Budget Summary: Land and Surface Water System*, on page 80, but further described for the historic and current conditions in Table 2A-1, on page A-3.¹ As represented in both the inflow and outflow portions of the table, quantities listed for managed wetlands under the “historical” heading are significantly greater than quantities listed under the “current” and various future conditions. We are unable to find any basis for this reduction beyond anecdotal references in the BBGM about a recent model update affecting hydraulic conductivity.²

Absent additional explanation as to why these quantities are significantly lower, the GSP appears to anticipate a reduction in managed habitat acres and function. Clarification regarding total assumed acres and expected applied water requirements would address this concern.

Our comments are summarized as follows:

1. Identification of managed wetlands: Audubon appreciates that VGSA has identified and specifically included managed wetlands in maps and water budgets. However, details regarding managed wetland acres and assumed evapotranspiration (ET) rates are lacking.
2. Water budget: Inclusion of managed wetlands as a specific component of the water budgets (e.g. Table 2-7) is appreciated. While reference is made to the BBGM regarding assumptions, review of the BBGM model documentation did not reveal details regarding the assumed managed wetland acres within the Vina subbasin under historic, current, or future water budgets nor the assumed ET and related details that would drive the calculation. As such, Audubon is concerned that the future conditions inadequately account for the water needs of managed wetlands, which are likely increasing under climate change.
3. Identification of data gaps: The lack of information regarding the water needs for managed wetlands should be identified as a data gap in the GSP. Specifically, on page 74, the GSP notes that agricultural demands (including managed wetlands) and groundwater pumping were estimated using the BBGM. The BBGM indicates ET was determined using remote sensing data

¹ Table 2A-1 provides annual values for the water budget for 2000 through 2018. Inflow and outflow quantities for managed wetlands are consistent across this period until 2015 through 2018 when values are significantly reduced with no explanation.

² “...a reduced hydraulic conductivity value was assigned to each element for ponded land uses (rice and wetlands) to avoid unreasonably high applied water estimates due to high deep percolation rates.” Butte Basin Groundwater Model: Model Documentation v1.0, August 2021, page 18.

and corresponding crop coefficients, but does not list a crop coefficient for managed wetlands. The appropriate water needs of managed wetlands do not appear to have been adequately represented in the water budgets, particularly given the unexplained reduction in water demands for managed wetlands in current and future water budgets.

4. Consideration of managed wetlands: While managed wetlands are appropriately included in the GSP separate from groundwater dependent ecosystems, there is no discussion of the impacts of the GSP on managed wetlands. Again, the reduction in water from the historic to current and future water budgets points to a serious reduction in habitat acreage or function, but there is no discussion of wetland impacts. The GSP would also be strengthened by including information on the role managed wetlands can have as part of projects and management action solutions. Managed wetlands provide opportunities for multi-benefit recharge and need to be part of any investigations into groundwater allocations and resulting policies.

Draft Groundwater Sustainability Plan Page-by-Page Comments

Additional page-by-page comments on VGSA’s draft GSP are detailed below. We welcome any follow up questions and look forward to seeing the issues raised below addressed in the final GSP submission in January 2022.

Figure 1-6: Land use map should also show the location of managed wetlands.

P. 22: Does the category “surface water users” include any managed wetlands that apply surface water to meet the managed wetland water needs or are managed wetlands only included in the category “environmental users of groundwater”?

P. 68: The category “Not Likely a GDE Due to Supplemental Water Supplies” indicates a determination was made for managed wetlands that rely on supplemental water to meet applied water needs. Elsewhere in the GSP, information regarding whether this supplemental water is pumped groundwater or applied surface water is lacking (see related comment for page 22). Additional details regarding the managed wetland acres, applied water needs, and water sources should be referenced. As noted previously in this comment letter, review of the BBGM indicates the information is not clearly documented in this referenced document either.

P. 73, Table 2-6: Why were surface water diversions for the current condition baseline water budget limited to 2015 and 2016? These years reflect low surface water availability due to drought constraints and State Water Resources Control Board imposed water right curtailments. For managed wetlands that may rely on surface water, this would be a misrepresentation of current and long-term needs. Combined with information in Table 2-7 and Table 2A-1 where the water budgets for these two years show significantly lower inflow and outflow quantities for managed wetlands than for prior years, there is concern that the current budget underestimates managed wetland water needs. Since the current condition assumptions regarding water supplies are carried forward to the future conditions, the misrepresentation of managed wetland water supplies due to limiting to 2015 and 2016 may incorrectly affect future water budgets and results.

P. 74: The bullets explaining the water budget procedures do not provide the necessary details regarding assumptions specifically made for managed wetlands. For instance, groundwater pumping is estimated by estimating total demand then subtracting applied surface water quantities – referencing the BBGM as the source document for the assumptions. Upon reviewing the BBGM draft documentation, the details regarding these assumptions are also not provided so it is

unclear what assumptions were made to calculate managed wetland demands and what surface water quantities were available. There needs to be improved documentation in the BBGM if it is a primary source for the water budgets presented in the GSP.

P. 80, Table 2-7: Inflow and outflow components for the row labeled “managed wetlands” shows a significant decrease in quantities between the historic water budget and the current and future water budgets. As noted in prior comments, the basis for this significant reduction is unclear and raises concerns that the total acres or the total water needs are misrepresented or otherwise artificially decreased.

P. 82, Table 2-8: The same concern as expressed for Table 2-7 is presented in this table.

P. 83: The GSP notes that evapotranspiration (ET) is from several beneficial uses, including managed wetlands. However, details regarding the ET assumptions for managed wetlands are lacking. These special habitats can have several different water needs depending on how they are managed and the target species they are intended to benefit (e.g. fall flood up for habitat versus spring irrigation for waterbird feed). This same statement is repeated for each water budget condition on subsequent pages in the GSP (e.g. future conditions). This comment applies to each.

P. 145, Flood MAR/Surface Water Supply and Recharge Scoping: Please include Audubon as a participant in scoping for recharge opportunities. Managed wetlands can provide unique opportunities to create recharge and habitat benefits.

P. 160, Groundwater Allocation: This potential action should indicate that considerations of public benefit needs, such as managed wetlands, will be included when evaluating any groundwater extraction limits.

Thank you for your consideration of Audubon California’s comments. If you would like to discuss these comments as you update your GSP, please do not hesitate to contact me at (916) 737-5707 or via email at samantha.arthur@audubon.org.

Sincerely,

A handwritten signature in black ink, appearing to read 'Samantha Arthur', written in a cursive style.

Samantha Arthur
Working Lands Program Director
Audubon California

Thank you for the opportunity to comment on the Vina GSA GSP.

The Butte Environmental Council (BEC) represents hundreds of members, most of whom are Butte County voters, and thousands of followers on digital media. BEC's stance on the issue is outlined below, and also speaks for the thousands of local voters and stakeholders that will be affected by this issue should it come to pass.

Below please find the details addressing the **matters of concern** of the Vina GSA GSP submitted on behalf of the Butte Environmental Council:

1. Overestimating Water Supply

The Butte Environmental Council is concerned that the basin settings does not take into account climate change and the changing water supply. With warmer weather, we will have reduced water supply from the Sierra Snowpack, with up to 48-65% by the end of the century¹. Droughts will likely become more frequent and persistent in the 21st century. With precipitation changes, and extreme events, there are projected to be more intense rainfall, and more intense flooding that will change how much water percolates down into our aquifers. With these changes, the Vina GSA needs to be conservative with the estimates of water that the subbasin will recharge annually. With the potential overestimation of the water supply, undesirable results will occur.

2. Groundwater Dependent Ecosystem & the City of Chico Urban Forest

The Butte Environmental Council is concerned that the City of Chico Urban Forest is not included as a potential Groundwater Dependent Ecosystem, to be protected and ensure healthy groundwater levels. The Urban Forest, which is a climate change adaptation and mitigation strategy, used to draw down carbon, shield residents from the scorching heat on sidewalks, and reduce residents energy bills, utilizes the shallow portion of the Tuscan Aquifer after establishment. This critical green infrastructure needs to be protected and the groundwater levels need to reach the roots of the Urban Forest.

3. Prioritization of Demand Management

Demand management and reuse of water need to be prioritized and a central part of our groundwater management toolkit, not just supply expansion. The Butte Environmental Council does not support taking surface water to use instead of groundwater, especially from PID. There could be complications once the Town of Paradise has rebuilt, and has the increased water demand. With the fact that the subbasin is only in 10,000 acre feet of overdraft, and that the Chico residents

¹ <https://water.ca.gov/Programs/All-Programs/Climate-Change-Program/Climate-Change-and-Water>

were able to conserve 32% during the last drought, demand management projects need to be implemented before any water supply expansion projects are implemented.

Below please find the details addressing the **matters of support** of the Vina GSA GSP submitted on behalf of the Butte Environmental Council:

1. Wastewater Recycling Project

Wastewater recycling is a great project that reduces the demand and stress on the groundwater supply, and needs less treatment than water used for potable use.

2. Residential Conservation Project

Demand management through residential conservation is an excellent strategy to stay within the groundwater supply boundaries of the basin. The City of Chico/CalWater was able to reduce their water consumption by 32%² by way of residential conservation.

3. Agricultural Irrigation Efficiency Project

Agricultural irrigation efficiencies can also protect water quality, and reduce demand on the aquifer. Water conservation and efficiencies within agriculture in the subbasin needs to be a key component of reaching groundwater sustainability. With adoption of efficient irrigation practices that could reduce groundwater demand up to 4,000 acre feet annually, and that the Vina subbasin is in overdraft of 10,000 acre feet, this project alone could be a major element of getting the basin to sustainable groundwater levels.

4. Community Monitoring Program and Community Water Education Initiative

Educating the community on what is happening with water and bringing awareness to the importance of water in Butte County is critical to creating buy-in on water conservation practices, and ensuring groundwater sustainability.

5. Rangeland Management and Fuel Management for Watershed Health Projects

Regenerative grazing practices improve water holding capacity and can improve recharge ability within the basin by increasing organic matter in the soil. Regenerative farming practices, such as cover cropping, no-till, and compost application can further improve water utilization on farmland. The Butte Environmental Council supports the rangeland management, but encourages the Vina GSA to include regenerative farming practices in the menu of projects to get to sustainable groundwater levels. Each 1% increase in soil organic matter would increase water holding capacity by 27,000 gallons of water per acre, thereby improving water utilization and reducing water demand on both rangeland and farmland³.

Fuel reduction and management can improve groundwater recharge and water quality.

6. Removal of Invasive Species Project

This is an excellent project. Removal of high water consuming invasive species like arundo can reduce water demand, increasing the amount of water available for groundwater recharge.

² <http://projects.scpr.org/applications/monthly-water-use/california-water-service-company-chico-district/>

³ https://www.nrcs.usda.gov/Internet/FSE_DOCUMENTS/stelprdb1082147.pdf

7. Inclusion of Valley Oaks in the Sustainability Indicators

Groundwater-dependent ecosystems are an important consideration under SGMA, and it is important to protect the shallowest positions of the aquifer upon which critical groundwater dependent ecosystems rely. The valley oaks are a keystone species in the area, and the canopy of the urban forest is vital for climate adaptation and mitigation. We seek to ensure that groundwater dependent ecosystems are protected in the region, and support the inclusion of Valley Oaks in the minimum thresholds for declining groundwater levels in the Vina GSA GSP.

Butte Environmental Council (BEC) has been a leading 501(c)(3) environmental non-profit in Butte County since 1975, dedicated to environmental issues that threaten the land, air, and water of our communities. BEC is a grassroots organization supported by over 200 paying members, hundreds of volunteers and donors, dozens of local business sponsors, over 3,500 followers on social media, and over 4,000 subscribers to our monthly electronic newsletter. Throughout each year, BEC offers citizens many chances to engage in environmental education, advocacy and stewardship. BEC provides position statements when the organization's leaders recognize a regional environmental threat to citizens.

Thank you for the opportunity to provide comments on this important project. Please contact our Executive Director, Caitlin Dalby, at caitlin.dalby@becnet.org with any questions.

RE: Comments on the draft *Vina Groundwater Sustainability Plan*

Executive Summary

The summary states:

"The interests and vulnerability of stakeholders and groundwater uses in these Management Areas vary based on the nature of the water demand (agricultural, domestic, municipal)" Water demand for the environment must be included. GDEs include upland and riparian valley oak groves, small stream flow, GD urban forests.

"groundwater use has increased and as forces ranging from population growth to climate change play out," This sentence ignores the fact that increased cross-boundary flows that may result from expanded demand west of the river (primarily agriculture and water-market-driven aquifer exercise) is at play. This threat to meeting our management goals must be acknowledged and addressed in interbasin coordination/communication process yet to be developed.

"Groundwater storage in Subbasin is relatively stable except in the areas noted above with depressions." The identification of localized cones of depression is valid but it is important to recognize long-term basin declines that occur due to cross-boundary flows influence the baseline water levels. In general (depending on soil conditions and strata) the greater the distance or depth of groundwater pumping and water levels in the VGSA, the lower the magnitude but the longer the timescale of depletions. Consequently, the ultimate effects in the Vina of pumping west of the river can occur significantly after pumping starts, or even after pumping has ceased. The timescales involved in aquifer responses to pumping and other stresses can be on the order of decades, making it difficult to associate cause with effect. As such, monitoring must account for this lag in impacts. In general, the longer the timeframe for effects to be observed at a given monitoring point once they become evident, the longer those effects will persist.

"If the water table beneath the stream lowers as a result of groundwater pumping, the stream may disconnect entirely from the underlying aquifer." A stream that ceases to flow once it enters the alluvial basin is entering the aquifer at that point. The deeper the aquifer level the more of the streambed is dewatered and the earlier. So while a stretch of the creek may be "disconnected" the creek itself is still connected. Mr. Toccoy Dudley, a Department hydrogeologist with the Northern District in Red Bluff, wrote in 2000: At any location in the basin, the gradient between the surface water and groundwater system is directly proportional to the head differences (water surface elevation difference) between the two hydrologic systems. The larger the head differences the higher the gradient and the higher the recharge rate....The shorter the horizontal distance over which the head change occurs increases the recharge rate dramatically. An example of this would be pumping next to a river would induce a much higher recharge rate from the surface water system than the same pumping many miles away.....increased extraction causes the groundwater levels to decline, which increases the head

difference between the groundwater and surface water systems, and consequently increases the gradient and recharge rate. In short, the more you pump, the more you can pump, to a point. Anecdotal and archeological evidence indicates the small streams of the Vina SB were perennial during pre-pumping eras.

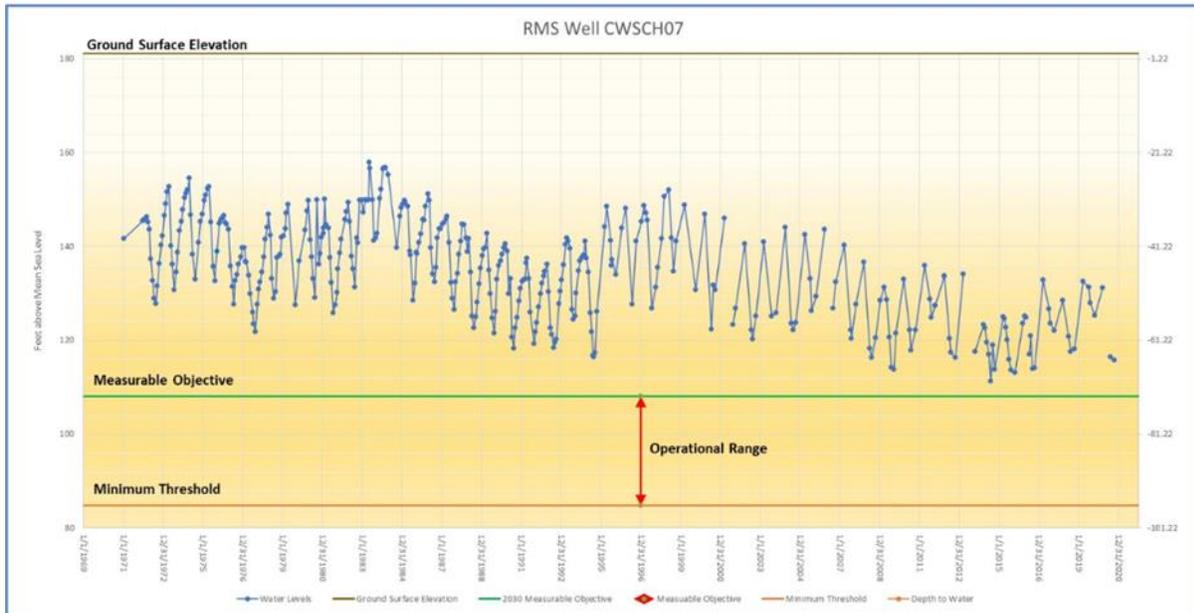

Figure ES-7: Representative Monitoring Site For Groundwater Levels With Relationship Of Measurable Objectives, Minimum Thresholds and Operational Range

The sample hydrograph is one of several that I have reviewed in Appendix 3-b of the GSP that have disturbing MO and MT levels. The MO is below the historic low, not the appropriate level to designate the top of the operational range. The MT as defined in other parts of the GSP, is purported to designate “the point at which Undesirable Results may BEGIN to occur.” But undesirable results will begin much earlier in the operational range. The historic low of this hydrograph is above the 80’ max rooting depth of native phreatophytes. The MT is significantly lower than 80’ bgs. Furthermore, the lower water table will dewater longer reaches of streams earlier in the season and persist later in the year. The operational range proposed is pessimistic in meeting goals that would avoid triggering Undesirable Results. Wise resource management strives to improve conditions that have been degraded by human development. Accepting degraded status quo or planning for increased degradation may be realistic given the human inclination to ambitiously convert resources into useful products. But the term “sustainable” implies we have the capacity to identify and honor carrying capacity while devising demand flexibility strategies to meet evolving climate conditions. Robust Management Objectives reduce the probability of careening toward Management Thresholds. Our MO levels can strive to improve conditions without risk of State management takeover. Water code § 354.30. Measurable Objectives (g) An Agency may establish measurable objectives that exceed the reasonable margin of operational flexibility for the purpose of improving overall conditions in the basin, but failure to achieve those objectives shall not be grounds for a finding of inadequacy of the Plan.

Chapter 2 Basin Setting

2.3.4 Water Budget Estimates

2831 "Other components are more difficult to measure or do not have measured values readily available (e.g., deep percolation, subsurface flows, groundwater pumping, surface water-groundwater interaction, etc.) and are estimated using the BBGM." It is unclear how the BBGM estimates Western Boundary Net Outflows 56,100- 65,000 AFY.

This map from the first draft of the Vina Water Budget presentation last year estimated a total of 200k AFY flowing from the east out of Butte into Colusa. The first draft of the Butte Subbasin Preliminary Basin Setting Results indicated 261k AFY of water flow from the west into the Butte basin from Colusa. These large discrepancies in outflow estimates do not inspire confidence in the Water Budget, the identification of who is responsible for GW declines or the efficacy of proposed recharge efforts.

"the ultimate effects of pumping can occur significantly after pumping starts, or even after pumping has ceased. The timescales involved in aquifer responses to pumping and other stresses can be on the order of decades, making it difficult to associate cause with effect. As such, monitoring must account for this lag in impacts. In general, the longer the timeframe for effects to be observed at a given monitoring point once they become evident, the longer those effects will persist, even if the pumping causing the effects is halted immediately." Davids Engineering 2014. Prepared for NCWA, Sacramento Valley Groundwater Assessment Active Management – Call to Action, pp. 14-15.

We know that interbasin flows are dependent on conditions in adjacent basins. "3014 Western boundary net outflows represent Sacramento River gains from groundwater and subsurface outflows to the Corning Subbasin. The split between these outflows is uncertain at this time and identified as a data gap." This significant data gap will present challenges as the impacts of GW pumping are not immediate and can take months or years to occur. The emerging California Water Market is a factor that is going to complicate regional water budget estimates.

BCWRC's Drought Task Force intention to evaluate the cumulative impacts of Water Transfer Programs (including GW Substitution water market transactions) and Supplemental Groundwater Pumping Operations in the Northern Sacramento Valley is essential to understand sub basin water budgets.3251

The failure of the GSP to attempt an estimate of interbasin subsurface flow along the Western Boundaries invalidates the Water Budget on which much of the GSP uses as a foundation. It is inappropriate to explain that "*Characterization of Interbasin Flows and Net Outflows along Western Boundary*" is placed in the "Next Steps" category. Water Code § 354.16 explains "Groundwater Conditions Each Plan shall provide a description of current and historical groundwater conditions in the basin, including data from January 1, 2015, to current conditions, based on the best available information that includes the following: (a) Groundwater elevation data demonstrating flow directions, lateral and vertical gradients, and regional pumping patterns, including: (1) Groundwater elevation contour maps depicting the groundwater table or potentiometric surface associated with the current seasonal high and seasonal low for each principal aquifer within the basin." Code § 354.18. "Water Budget (a) Each Plan shall include a water budget for the basin that provides an accounting and assessment of the total annual volume of groundwater and surface water entering and leaving the basin, including historical, current and projected water budget conditions...(3) Outflows from the groundwater system by water use sector, including ... subsurface groundwater outflow." Early basin-setting drafts of the Vina, Butte and Colusa sub-basins showed large discrepancies in the modeled subsurface aquifer outflow patterns. The Butte Basin Groundwater Model has no capacity to quantify subsurface GW flow out of the western boundary of the sub-basin. The present draft recognizes the data gap and inadequacy of regional modeling that characterizes the water budget of inflow and outflow.

SGMA regulations require Each Plan to contain a water budget for the basin that identifies discharges including subsurface groundwater outflow. The Butte County Drought Task Force recognizes that Groundwater extractions outside the Vina boundaries such as the past and present Water Transfer Programs and Supplemental Groundwater Pumping Operations in the Northern Sacramento Valley may have enduring cumulative impacts on Vina's water budget.

2.1.2.4 Groundwater Recharge Areas

"Groundwater recharge is the downward movement of water from the surface to the groundwater system." Some recharge occurs from upward movement. Piezometric pressure from the semi-confined portions of the Tuscan System allows water to move upward recharging into or supporting alluvial unconfined aquifers if sufficient pressure exists. Line 1940 explains; "*In locations where groundwater levels in the shallower wells are lower than in the deeper wells, the gradient indicates upward movement of groundwater, with a similar relationship defining the volume of upward flow.*" Conversely the alluvial shallow aquifer can leak downwards if the piezometric elevation is reduced. Line 1937: "*When groundwater levels in the shallower wells are higher than in the deeper completions, the gradient indicates downward movement of groundwater. The volume of downward flow is proportional to the gradient and the hydraulic conductivity between the shallow and deep measurement points.*" The USDA groundwater atlas [https://pubs.usgs.gov/ha/ha730/ch_b/B-text3.html] explains this well-known water fact: "By the early 1960's, intensive ground-water development had significantly lowered water levels and altered ground-water flow patterns in the Central Valley aquifer system. By far the most dramatic impact of development was in the San Joaquin Valley, where water-level declines in the confined part of the aquifer system were locally more than 400 feet. Although predevelopment flow was toward the San Joaquin River throughout most of the basin, large withdrawals from deep wells in the western and southern parts of the aquifer system changed the direction of horizontal flow in the confined part of the system until the water moved toward the withdrawal centers. Also, because the magnitude of the withdrawals caused hydraulic heads in the confined parts of the aquifer system to fall far below the altitude of the water table, the vertical hydraulic gradient was reversed over much of the San Joaquin Valley. As a result, much of the water in the upper unconfined zone of the aquifer system that flowed laterally toward the river under predevelopment conditions leaked downward through the confining beds into the lower confined aquifer after development...Ground-water development in the San Joaquin Valley has reduced the effectiveness of the confining beds within the aquifer. Thousands of wells with casings perforated for much of their length have been drilled through the clay confining units. Where these wells are open to the unconfined and confined aquifers, they allow virtually unrestricted vertical flow through the well bore. The amount of water that flows downward through one large-diameter well has been estimated to be equivalent to the natural leakage through the "E-clay" over an area of approximately 7 square miles. During the peak of the withdrawal season, the net downward flow may be, on average, as much as 0.3 cubic foot per second per well." Significant Depressurization of the regional confined aquifer can take place within and outside of the Vina sub basin. Well-casings that have perforations at shallow and deep levels interrupt the confining layers and increase the vertical flow. Lines 1456-1460 indicate there is this type of potentially interbasin leakage in the Vina SB "*Aquifer testing conducted as part of the Lower Tuscan Aquifer study (Brown and Caldwell, 2013) indicated there is also the potential for Upper Watershed recharge in the shallow aquifer interval to move down to greater depths due to irrigation pumping, causing a mixing of recharge sources in the intermediate and possibly deeper aquifer zones in the Vina South Management Area.*" Line 1469 discusses "*Additional*

recharge through management activities of flood flows or irrigation practices has potential in the Vina Subbasin..." but does not discuss how the recharged water can migrate through the deep aquifer into adjacent sub-basins that are being pumped.

2.1.5 Groundwater Producing Formations presents an incomplete overview of the producing geology and fails to quantify the robust yields of the Tuscan even while quantifying the production amounts available in less important aquifer units, line 1614: "*Wells penetrating the sand and gravel units of the Riverbank and Modesto Formations produce up to about 1,000 gallons per minute (gpm)*" The Update on the Stony Creek Fan aquifer Performance Testing [<http://cetehama.ucdavis.edu/files/135217.pdf>] indicated that that Lower Tuscan can produce 2,500-3,000 gpm. The GCID and others are exploiting/depressurizing this extremely productive aquifer. The cumulative demand of the wells exercising the lower Tuscan is undoubtedly impacting water levels in all aquifer layers in the 4-county basin.

2.1.8.2 Beneficial Uses "*Water produced from the principal aquifer is primarily used to meet irrigation, domestic, and municipal water demand.*" This sentence should include "*environmental demand*". Groundwater and surface water are historically and, in many cases, currently connected. Beneficial uses must include the benefits to ecosystems including Groundwater Dependent upland vegetation. According to the State Water Board delineation of beneficial uses: [https://www.waterboards.ca.gov/rwqcb2/water_issues/programs/planningtmdls/basinplan/web/bp_ch2.html]

2.1.3 COLD FRESHWATER HABITAT (COLD)

Uses of water that support cold water ecosystems, including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

2.1.14 PRESERVATION OF RARE AND ENDANGERED SPECIES (RARE)

Uses of waters that support habitats necessary for the survival and successful maintenance of plant or animal species established under state and/or federal law as rare, threatened, or endangered.

2.1.18 FISH SPAWNING (SPWN)

Uses of water that support high quality aquatic habitats suitable for reproduction and early development of fish.

2.1.19 WARM FRESHWATER HABITAT (WARM)

Uses of water that support warm water ecosystems including, but not limited to, preservation or enhancement of aquatic habitats, vegetation, fish, or wildlife, including invertebrates.

2.1.20 WILDLIFE HABITAT (WILD)

Uses of waters that support wildlife habitats, including, but not limited to, the preservation and enhancement of vegetation and prey species used by wildlife, such as waterfowl.

Beneficial uses of streams that have intermittent flows, as is typical of many streams in the region, must be protected throughout the year and are designated as "existing."

2.2 Groundwater Conditions; • "*Wells showing depths to first encountered groundwater deeper than 500 feet were eliminated from the data set.*" The rationale behind this limitation is unclear. If there is significant piezometric pressure identified in the water encountered below 500' it should be included in the analysis. The hydrographs in this section measure a shallow portion of the system. It is likely that the groundwater flow volumes would be stimulated when the pressurized portion of the aquifer is

depressurized by major production operations. The cumulative effect of these extractions may be the cause of the decline in the seasonally fluctuating regional aquifer levels. The failure to evaluate the effect of confined/semi-confined piezometric pressure dynamics on groundwater conditions must be remedied. line 2143 identifies the existence and importance of this pressure in relation to subsidence but there is no other mention of piezometric pressure. *“As the pressure created by the height of water (i.e., head) declines in response to groundwater withdrawals, aquitards between production zones are exposed to increased vertical loads.”* The measurement of piezometric pressure is important for groundwater monitoring. It allows us to determine the level and flow patterns of the groundwater. Omitting a discussion of piezometric pressure when discussing groundwater conditions in our region is like ignoring blood pressure during a human physical exam.

Line 1996

“Since the year 2000, there has been a cumulative decline in March 1 groundwater storage of about 400,000 acre-feet (AF). This indicates the cycles of groundwater pumping are not in balance with the cycles of recharge that replenish the aquifer, and that groundwater depletion has occurred consistent with long-term decline in groundwater levels.” Without a regional GW model and a record of pumping throughout the Tuscan basin it is impossible to identify pumping in the VGSB as the sole demand resulting in the decline in GW storage.

Line 2017

“Development of groundwater quality-related Sustainable Management Criteria for the Vina Subbasin is not intended to duplicate or supplant the goals and objectives of ongoing programs including those by Butte County, the SVWQC and the State Drinking Water Information System (SDWIS) [SWRCB Geotracker/GAMA website, the California Department of Toxic Substances Control (DTSC) EnviroStor website, and the Environmental Protection Agency’s (EPA) National Priorities List (NPL)].” GW pumping stimulates the movement of toxic plumes through the aquifer system. Advection is the movement of dissolved solute with flowing groundwater. The amount of contaminant being transported is a function of its concentration in the groundwater and the quantity of groundwater flowing, and advection will transport contaminants at different rates in each stratum. Who are the personnel in the VGSA that will be tracking these data and correlating it to various GW pumping regimes and flow patterns?

Line 2298

“There is no indication in the streamflow data to suggest groundwater interactions that contribute to the streamflow behavior. Similar conditions would be expected for other creeks that traverse the Vina Subbasin (Little Chico, Sycamore, Rock, and Butte Creek) since they flow across a similar fan topography and similar shallow subsurface geology. The overall conclusion from this study in relation to interconnected surface water is that, for significant portions of the year, the upland creeks in the Vina Subbasin would be classified as disconnected streams and the surface water would be considered “completely depleted” as defined under SGMA.” Water code chapter 23 explains *“(o) “Interconnected surface water” refers to surface water that is hydraulically connected at any point by a continuous saturated zone to the underlying aquifer and the overlying surface water is not completely depleted.”* As I read Water Code it is clear that streams flowing out of the foothills are hydraulically connected until they reach a point where the aquifer has been depleted below stream level at which point the stream looses as it recharges the evacuated aquifer. As the GW level declines the stretch of dewatered stream expands. Spatial and temporal dewatering monitoring is a critical GDE function of a GSA. The California

Department of Fish and Wildlife has specific GDE recommendations that must be implemented in the VGSA: [<https://nrm.dfg.ca.gov/FileHandler.ashx?DocumentID=170185&inline>]

“GROUNDWATER DEPENDENT ECOSYSTEMS (GDES)

1. How will groundwater plans identify GDEs and address GDE protection?
2. How will GSAs determine if GDEs are being adversely impacted by groundwater management?
3. If GDEs are adversely impacted, how will groundwater plans facilitate appropriate and timely monitoring and management response actions?

INTERCONNECTED SURFACE WATERS (ISW)

1. How will groundwater plans document the timing, quantity, and location of ISW depletions attributable to groundwater extraction and determine whether these depletions will impact fish and wildlife?
2. How will GSAs determine if fish and wildlife are being adversely impacted by groundwater management impacts on ISW?
3. If adverse impacts to ISW-dependent fish and wildlife are observed, how will GSAs facilitate appropriate and timely monitoring and management response actions.”

According to a study on small streams flowing through the Vina SB: “Nonnatal rearing of juvenile Chinook salmon was documented in several intermittent tributaries to the Sacramento River. Condition factors and length measurements of juvenile chinook captured in the intermittent tributaries were compared with those captured in the mainstem Sacramento River. The data suggests that juvenile chinook rearing in the tributaries grew faster and were heavier for their length than those rearing in the mainstem. Faster growing fish smolt earlier, and may enter the delta earlier in the year before low water and pumping degrade rearing habitat.” Intermittent Streams as Rearing Habitat for Sacramento River Chinook Salmon.

https://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/deltaflow/docs/exhibits/swrcb/swrcb_maslin1997.pdf

The unregulated streams that flow into the Sacramento River are leaking into drained aquifers. Dan Wendell of The Nature Conservancy, a panelist at a workshop held by the California Natural Resources Agency, explained “since the 1940s, groundwater discharge to streams in the Sacramento Valley has decreased by about 600,000 acre-feet per year due to groundwater pumping, and it’s going to decrease an additional 600,000 acre-feet in coming years under status quo conditions due to the time it takes effects of groundwater pumping to reach streams.”

https://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/california_waterfix/exhibits/docs/CSPA%20et%20al/part2/aqua_282.pdf

2.2.7 Groundwater Dependent Ecosystems

2488 Not Likely a GDE Due to Adjacency to Irrigated Agricultural Fields

2504 Not Likely a GDE Due to Dependence on Agricultural-dependent Surface Water

GDEs were incorrectly removed in areas adjacent to irrigated fields due to the presence of surface water. However, GDEs can rely on multiple water sources – including shallow groundwater receiving inputs from irrigation return flow from nearby irrigated fields - simultaneously and at different temporal/spatial scales. Basins with a stacked series of aquifers may have varying levels of pumping across aquifers in the basin, depending on the production capacity or water quality associated with each aquifer. If pumping is concentrated in deeper aquifers, SGMA still requires GSAs to sustainably manage

groundwater resources in shallow principal aquifers, that support springs, surface water, and groundwater dependent ecosystems. Areas in proximity to irrigated land can still potentially be reliant on shallow groundwater aquifers, and therefore should not be removed solely based on their proximity to irrigated fields.

3014 "*Western boundary net outflows represent Sacramento River gains from groundwater and subsurface outflows to the Corning Subbasin. The split between these outflows is uncertain at this time and identified as a data gap.*" The subsurface outflow analysis must be expanded to include outflows into other nearby sub basins including Butte and Colusa. Increased GW extractions due to crop changes, "emergency" supplemental GW pumping, and GW substitution transfers is likely to increase subsurface flows over time. Butte Counties nascent Drought Impacts Analysis Study plans to compile the 2021 water transfer programs (April 2021-December 2021) from Butte, Tehama, Glenn, Colusa, Yuba and Sutter counties.

The report will include a brief description of the programs, amount of water transferred, recipient of water, whether surface water or groundwater substitution is utilized, destination of transferred water, etc. including maps. Analysis of the transfer programs will evaluate the cumulative impacts of the programs' impacts on water supplies and demands. This type of annual evaluation must be ongoing as demand/supply conditions evolve and consider "timescales involved in aquifer responses to pumping and other stresses can be on the order of decades, making it difficult to associate cause with effect. As such, monitoring must account for this lag in impacts. In general, the longer the timeframe for effects to be observed at a given monitoring point once they become evident, the longer those effects will persist, even if the pumping causing the effects is halted immediately." [1]

[1] Davids Engineering 2014. Prepared for NCWA, Sacramento Valley Groundwater Assessment Active Management – Call to Action.

Line 3016 **Water Banking Stimulation of sub surface flows** "*It is anticipated that this data gap [sub surface flows] will be addressed through future refinements to the BBGM and through coordination and collaboration with neighboring subbasins as part of GSP implementation.*" The coordination and collaboration with neighboring subbasins is, at best, an forthright sharing of information and unbiased evaluation of model results. However, the VGSA would be naïve to ignore the special interests of key players in the Northstate Water World that may inspire some purveyors to profitably engage in the emerging California Water Market with less regard to the interests of GDEs and water users that are not participating in Transfer/sales that "exercise" the shared regional aquifer while promising to use PMAs to refill drained aquifer water banks.

3181 **Habitat Monitoring Deficit** "It is anticipated that these uncertainties will be reduced over time through monitoring and additional data collection, refinements to the BBGM and other tools, and coordination with neighboring basins." The DGSP is deficient because significant monitoring infrastructure has yet to be funded and built in the shallowest portion of the aquifer system that GDEs rely upon. According to the 2007 DWR/NCWA Sacramento Valley Water Resource Monitoring, Data Collection and Evaluation Framework; "The long-term health of riparian vegetation, wetland species, and number of other native habitat are commonly associated with maintaining a minimum range of groundwater levels and an appropriate level of interaction between surface water and groundwater resources. The lowering of groundwater levels due to natural climatic changes or the interception of

groundwater underflow to surface water systems due to the increased groundwater extraction associated with water management programs, have the potential to impact the native habitat areas. Baseline habitat monitoring is an important data collection objective because it allows for a better understanding of the existing water resource requirements of the native habitat and the evaluation of potential impacts associated with potential changes in water resource management practices. In order to identify potential habitat impacts associated with potential changes in water management practices, a program-specific network of shallow monitor monitoring wells should be developed to detect changes in water levels over the shallowest portion of the aquifer. In evaluating impacts to certain wetlands species, it is important to discern both the rate of groundwater level change, as well as the cumulative change over the entire year. Data collection and monitoring frequency should be appropriately selected to support the temporal and long-term evaluations.”

https://www.waterboards.ca.gov/waterrights//water_issues/programs/bay_delta/california_waterfix/exhibits/docs/CSPA%20et%20al/part2/aqua_280.pdf

3266 3. SUSTAINABLE MANAGEMENT CRITERIA

3298 • *"MT– Quantitative threshold for each Sustainability Indicator used to define the point at which undesirable results may begin to occur."* The stated definition is the most egregious violation of common sense in the DGSP. Undesirable results BEGIN to occur even before historic low levels (the approximate upper reach of the operational range) are occur. Domestic well failures, destruction of GDEs and chronic lowering of groundwater levels occur at historic GW levels and would be exacerbated if the aquifer is managed within the Operational Ranges being proposed. I find the Plan to be deficient in protecting beneficial uses. Historic low GW levels shown in most of the Appendix 3-B hydrographs are still above the 80' max rooting depth of native and urban forest trees. The Minimum Threshold as defined in the GSP, is purported to designate “the point at which Undesirable Results may BEGIN to occur.” But undesirable results will begin much earlier in the proposed operational range shown in most of the hydrographs. These MTs are significantly deeper than 80' bgs. Furthermore, the lower water table will dewater longer reaches of streams earlier in the season and persist later in the year. Dan Wendell of The Nature Conservancy, a panelist at a workshop held by the California Natural Resources Agency, explained “since the 1940s, groundwater discharge to streams in the Sacramento Valley has decreased by about 600,000 acre-feet per year due to groundwater pumping, and it’s going to decrease an additional 600,000 acre-feet in coming years under status quo conditions due to the time it takes effects of groundwater pumping to reach streams.” The operational range proposed will not avoid triggering this and other significant irreversible Undesirable Results.

SGMA Regulations define “Measurable objectives” as “specific, quantifiable goals for the maintenance or improvement of specified groundwater conditions..” Setting GW level MOs below historic low levels does not meet this requirement. Most of the proposed MOs are below historic low levels. This is not the appropriate level to designate the top of the operational range. SGMA Water Code § 354.30 explains “An Agency may establish measurable objectives that exceed the reasonable margin of operational flexibility for the purpose of improving overall conditions in the basin, but failure to achieve those objectives shall not be grounds for a finding of inadequacy of the Plan.” The managers assure the public that the goal of the VGSP is to maintain GW levels above or near the MOs or that if the MT is approached/transgressed PMAs would be employed to bring water levels back to the MO or higher. The definition of the MT shows the “Operational Range” as the defined goal. The proposed broad

operational ranges fit the prescription for market driven groundwater banking but would result in many undesirable impacts to water users not participating in the rapidly emerging California Water Market.

3415 Water Bank Prescription "*The quantitative Vina Subbasin Undesirable Result for the Chronic Lowering of Groundwater Levels occurs when: Two RMS wells within a management area reach their MT for two consecutive years of non-dry year-types.*" Two years of operating at the MT level would destroy GDEs including the urban forest of Chico. The insulting caveat that it would be acceptable to forgive the extreme MT levels if they occur during 2 consecutive dry years would allow GW levels to decline below the MT and implies that artificial recharge during "wet" years is a mitigating option. This is another example of an operation prescription for conjunctive use water bank marketing.

3477 Cumulative impacts of regional pumping "*Groundwater levels are typically lower during dry years and higher during wet years. Superimposed on this four- to seven-year short-term cycle is a long-term decline in groundwater levels. In other words, groundwater levels during more recent dry-year cycles are lower than groundwater levels in earlier dry-year cycles.*" The DGSP fails here to identify the cumulative impacts of increased pumping in the regional shared Tuscan aquifer system that is driving the long-term trend in driving down the fluctuating hydrograph record. Management of connected groundwater systems is challenging for several reasons. First, the cumulative GW depletions caused by pumping depends on the spatial scale: in general (depending on soil conditions and strata) the greater the distance or depth between groundwater pumping and a monitoring well, the lower the magnitude but the longer the timescale of depletions. Consequently, the ultimate effects of pumping can occur significantly after pumping starts, or even after pumping has ceased. The timescales involved in aquifer responses to pumping and other stresses can be on the order of decades.

3703 Outside Hydrologic Influence "*hydrologic impacts outside of the Vina Subbasin, such as upper watershed development or fire-related changes in run-off, could result in impacts to streamflow, riparian areas, or GDEs that are completely independent of any connection to groundwater use or conditions within the Vina Subbasin.*" Since the deep Tuscan Aquifer System is recharged from the eastern basin foothills it is certainly appropriate to recognize impacts to groundwater use and conditions within the Vina SB resulting from fire related soil conditions and streamflow in the recharge area.

[<https://www.buttecounty.net/waterresourceconservation/SpecialProjects/StableIsotopeRechargeProject.aspx>]

Additionally, conditions in the down-gradient portion of the Tuscan System are worthy of evaluation as the VGSP evolves. The lower Tuscan Aquifer system is being developed as a water source west of the Sacramento River and is being evacuated with vigor especially during dry years. This may accelerate the rate of subsurface flow out of the Vina SB. The Glenn Colusa Irrigation District board pumped over 25K af of Tuscan groundwater for 2-3 months this summer to supplement their river allocation. This is on top of 10k af of groundwater substitution water transfers and even more surface water sales from "willing sellers" to "willing buyers" South Of Delta. The 35k/a/f is more water in 3 months than the Chico Urban Area pumps in a year. The State emergency declaration allows water purveyors like GCID to sidestep laws that require environmental review. GCID used district wells located 5-10 miles west of Chico that can pump 3KAF/minute. The Butte County Drought Task Force recognizes the importance of evaluating cumulative impacts of programs on water supplies and demands on the Vina SB may be significant and is

initiating a “Drought Impacts Analysis Study” that will compile and analyze the 2021 Water Transfer Programs and the Supplemental Groundwater Pumping Operations in the Northern Sacramento Valley. https://buttecounty.granicus.com/ViewerServlet.action?clip_id=1006&meta_id=157029

3776 Upland GDE Designation *“The Vina Subbasin specifically recognizes deep-rooted tree species, such as Valley Oak, that are common along riparian corridors in both upland streams and the Sacramento River. This connectivity is not well measured or understood in the Vina Subbasin at this time.”* The failure of the DGSP to accept the well-documented fact that deep rooted trees are not exclusively located along riparian corridors but are nonetheless dependent on the shallow aquifer.

US Forest Service Index of Species Information for Valley Oak explains the wide distribution of the Valley Oak ecosystem: <https://www.fs.fed.us/database/feis/plants/tree/quelob/all.html>

“Valley oak typically has several vertical roots that tap groundwater and extensive horizontal root branches. Vertical root depth has been measured as deep as 80 feet (262m) in some individuals. Best growth is attained when water tables are about 33 feet (10 m) below the surface. Historically, these forests extended 0.6 to 5.0 miles (1-8 km) on each side of major rivers. Valley oak cover was once extensive, extending through lowlands and into foothills.”

Limiting GDE evaluation to measurable impacts to interconnected streamflow is insufficient.

California Code of Regulations, Title 23 § 351. Definitions.

“(g) Identification of groundwater dependent ecosystems within the basin, utilizing data available from the Department, as specified in Section 353.2, or the best available information.

(m) “Groundwater dependent ecosystem” refers to ecological communities or species that depend on groundwater emerging from aquifers or on groundwater occurring near the ground surface.”

The DGSP, like other planning documents, promises on line 3785 “to fill these data gaps and the GSAs are committed to addressing these issues and develop appropriate SMCs for the Vina Subbasin.” But like other co-equal goals that assure balancing water supply with ecosystem health it is meeting the demand that takes precedence. In 2007 the DWR, NCWA and the State Water Board recognized the importance of habitat monitoring in their Sacramento Valley Water Resource Monitoring, Data Collection and Evaluation Framework

https://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/california_waterfix/exhibits/docs/CSPA%20et%20al/part2/aqua_280.pdf

“The lowering of groundwater levels due to natural climatic changes or the interception of groundwater underflow to surface water systems due to the increased groundwater extraction associated with water management programs, have the potential to impact the native habitat areas....In order to identify potential habitat impacts associated with potential changes in water management practices, a program-specific network of shallow monitor monitoring wells should be developed to detect changes in water levels over the shallowest portion of the aquifer.”

But there has been no investment in creating the network needed to collect baseline conditions or to monitor declines in this critical GDE preservation goal.

5. PROJECT AND MANAGEMENT ACTIONS

4412 5.2.3.1 Agricultural Irrigation Efficiency

4414 Butte County agriculture is a keystone feature of culture in the Vina SB. The importance of maintaining the viability of irrigated agriculture is of paramount importance. The results of the Vina GSA,

Agricultural Groundwater Users of Butte County, and Butte County Farm Bureau survey to evaluate current irrigation methods and practices, identify opportunities and methods to improve irrigation efficiency, determine potential issues preventing the adoption of efficiency practices, and provide recommendations for increasing participation in these practices were expected to be available in September 2021. A summary of the results would be helpful in evaluating opportunities to stabilize or reduce demand. Incentives to invest in efficient GW irrigation through grant funding and tax rebates are needed to maximize benefits. According to Valerie Kincaid "A project proponent maintains the right to water that is recharged whether it results from recharge projects or groundwater demand reduction projects (e.g., conservation, recycling)." Why is this not listed as a recharge project?

4449 5.2.3.2 Project: Residential Conservation The Estimated Groundwater Offset and/or Recharge: 100 acre-feet/year is certainly below the potential for urban efficiency. The voluntary expansion of xeriscape replacement of turf is evident and the adoption of efficient water using appliances is inevitable. The managers should review the successful urban conservation data from last decade to evaluate more realistic estimates of potential offset amounts.

4079 " As discussed in Section 4.1, the GSAs in the Vina Subbasin intend to further evaluate the SMC for interconnected surface waters to avoid undesirable results to aquatic ecosystems and GDEs. As additional data are collected and evaluated, the Vina Subbasin commits to developing additional SMC and installation of monitoring points, as appropriate, for specific stream reaches and associated habitat where there is a clear connection to groundwater pumping in the principal aquifer." Restricting monitoring points and GDE considerations to riparian proximities is insufficient for the protection of deep-rooted vegetation, both native trees and the Chico urban forest. According to the USDA Forest Service "Urban forests help to filter air and water, control storm water, conserve energy, and provide animal habitat and shade. They add beauty, form, and structure to urban design. By reducing noise and providing places to recreate, urban forests strengthen social cohesion, spur community revitalization, and add economic value to our communities."

[<https://www.fs.usda.gov/managing-land/urban-forests>]

The shallowest portion of the aquifer system that sustains this vegetation extends beyond riparian corridors. The Sacramento Valley Water Resource Monitoring, Data Collection and Evaluation Framework 2007 DWR NCWA

https://www.waterboards.ca.gov/waterrights/water_issues/programs/bay_delta/california_waterfix/exhibits/docs/CSPA%20et%20al/part2/aqua_280.pdf] recognizes the importance of establishing a monitoring network in the shallowest portion of the aquifer for this purpose: "The long-term health of riparian vegetation, wetland species, and number of other native habitat are commonly associated with maintaining a minimum range of groundwater levels and an appropriate level of interaction between surface water and groundwater resources. The lowering of groundwater levels due to natural climatic changes or the interception of groundwater underflow to surface water systems due to the increased groundwater extraction associated with water management programs, have the potential to impact the native habitat areas. Baseline habitat monitoring is an important data collection objective because it allows for a better understanding of the existing water resource requirements of the native habitat and the evaluation of potential impacts associated with potential changes in water resource management practices. In order to identify potential habitat impacts associated with potential changes in water management practices, a program-specific network of shallow monitor monitoring wells should be

developed to detect changes in water levels over the shallowest portion of the aquifer. In evaluating impacts to certain wetlands species, it is important to discern both the rate of groundwater level change, as well as the cumulative change over the entire year. Data collection and monitoring frequency should be appropriately selected to support the temporal and long-term evaluations.”

4477 5.2.3.3 Project: Streamflow Augmentation

“The project would primarily take place at Comanche Creek, Butte Creek, Little Chico Creek, and Big Chico Creek.” It is unclear how Little Chico Creek and Big Chico Creek would be integrated into this program since they are, apart from flood control infrastructure, unregulated by dams. If a project includes the application for a new right to recharge water, it will need to obtain a water right permit from the State Water Resources Control Board (SWRCB) through a surface water right application and a supplemental groundwater recharge form. The water right permit application would need to identify the “beneficial use” that the project intends to meet. Recharging groundwater is not considered a beneficial use, however, meeting the sustainable management criteria in a GSP may be determined to be a beneficial use.

Since this project is in the “Planned” category and is expected to move forward and be completed there must be more detailed information available to the public. The project description should be clear on permits that would be required to be negotiated with regulatory agencies such as CFW and the State Water Board.

4507 5.2.3.4 Flood MAR/Surface Water Supply and Recharge Scoping

This planned scoping project must include a detailed evaluation of the efficacy of up-gradient recharge efforts that may enhance extraction opportunities in down-gradient sub-basins that are developing new groundwater exploitation infrastructure to supply expanding permanent crop acres and engaging in water transfers that integrate the shared aquifer system into their transfer portfolio and have a history of using the same aquifer as an “emergency” supplemental water supply. The legal consequences of attempting MAR have been summarized by Ms. Kincaid and issues of aquifer privatization and potential water bank extirpation of Butte Chapter 33 protection remain unresolved and exacerbated by the expert analysis presented by the Public Policy Institute of California. **“County export ordinances prevent beneficial trades.** In the absence of state regulation of groundwater, county ordinances have protected local parties against injury from groundwater-related exports. But their export permitting hurdles are so high that they impede any transfers, including those that present no significant risk to local groundwater sustainability. In Butte County, for instance, it would take 18 months to go through all the steps to obtain a permit for a same-year groundwater substitution transfer. Once GSAs establish sustainability plans that address undesirable impacts of pumping, it should be possible to ease the coarser restrictions on this practice found in most county ordinances—which effectively preclude trades if they entail water leaving the county. If counties with restrictive groundwater export ordinances fail to amend their laws to conform to SGMA, the legislature should consider preempting local laws that discriminate against out-of-county uses or place undue burdens on groundwater and groundwater-substitution transfers that would not jeopardize sustainable groundwater management of the source aquifer.”

<https://www.ppic.org/publication/improving-californias-water-market/>

All the projects outlined in lines 4408-4663, as well as 4870 5.2.4.11 Project: Surface Water Supply and Recharge, whether they are conservation (demand reduction) or recharge (supply augmentation)

projects have the potential to carry the legal consequences of artificial recharge efforts. According to Kincaid [<https://www.vinagsa.org/files/4441577c7/PMA+Legal+Implications+Discussion+Paper.pdf>]

“A project proponent maintains the right to water that is recharged whether it results from recharge projects or groundwater demand reduction projects (e.g., conservation, recycling). If a project uses or obtains a surface water supply and recharges into the aquifer, the project proponent would have a legal right to the recharged water. Water does not legally become “common” or “native” supply available to overlying groundwater right holders unless it is abandoned by the project proponent.” The contentious issue of privatization of the aquifer that is used as a water bank must be resolved at the State level because local ordinances may be overridden by SGMA jurisdiction. The strategy of integrating the Tuscan Aquifer System into the State Water Supply is a long-standing threat to the balance of uses required to maintain the quality of life in the Vina SB. According to the Public Policy Institute of California, “County export ordinances prevent beneficial trades. In the absence of state regulation of groundwater, county ordinances have protected local parties against injury from groundwater-related exports. But their export permitting hurdles are so high that they impede any transfers, including those that present no significant risk to local groundwater sustainability. In Butte County, for instance, it would take 18 months to go through all the steps to obtain a permit for a same-year groundwater substitution transfer.

“Streamline transfer reviews while maintaining protections. Approval delays by federal, state, and local authorities often reflect uncertainties about the physical impact of a surface or groundwater transfer on other water users or the environment. Yet there are various ways to streamline the process while maintaining protections, for instance by conducting more up-front analysis of impacts through programmatic reviews, developing a “fast lane” for transfers below a certain size, developing a structured evaluative process for reviews, and establishing an after-the-fact process for balancing accounts to enable quicker approvals of time-sensitive activities.

“Develop more equitable local rules for groundwater substitution transfers. Well-run groundwater substitution programs can expand long-term water availability by more actively using local groundwater storage. Once GSAs establish sustainability plans that address undesirable impacts of pumping, it should be possible to ease the coarser restrictions on this practice found in most county ordinances—which effectively preclude trades if they entail water leaving the county. If counties with restrictive groundwater export ordinances fail to amend their laws to conform to SGMA, the legislature should consider preempting local laws that discriminate against out-of-county uses or place undue burdens on groundwater and groundwater-substitution transfers that would not jeopardize sustainable groundwater management of the source aquifer.”

The State may use emergency proclamation or legislative action to neutralize local control of water policy such as the Chapter 33 ordinance in Butte County. The broad operating range and historic low-level starting point (MO) that the VGSA consultants and staff have inserted into the VGSP will create the storage space needed to bank/sell water stored in the Butte Basin. The Kincaid white paper explains that Potential Management Actions “would allow the Vina GSA to protect the Vina subbasin and the implementation of the GSP from negative implications from artificial recharge projects through enactment of rules, ordinances and/or policies.” But her estimation that ordinances or policies that the GSA may adopt to ensure recharge projects are operating without adverse impact to the basin offer no assurance that the VGSA would have the capacity to successfully navigate the State prerogative to manipulate the emerging water market that intends to “Streamline groundwater substitution and water transfer permitting and approval processes by allowing consolidated basin-level environmental reviews

to facilitate water market transactions,” [<https://water.ca.gov/Programs/Groundwater-Management/Bulletin-118>]

4664 5.2.4.5 Community Monitoring Program *“This project would create routine water table monitoring programs for approximately 8,000 acres of Ecological Reserves in the region between lower Forest Ranch and Cohasset Road near Chico Airport, including the Big Chico Creek, Sheep Hollow, and Cabin Hollow tributaries.”* This project should be required to be implemented yesterday! Baseline habitat monitoring is an important data collection objective because it allows for a better understanding of the existing water resource requirements of the native habitat and the evaluation of potential impacts associated with potential changes in water resource management practices. To identify potential habitat impacts associated with potential changes in water management practices, a program-specific network of shallow monitor monitoring wells should be developed to detect changes in water levels over the shallowest portion of the aquifer. In evaluating impacts to certain GDE species, it is important to discern both the rate of groundwater level change, as well as the cumulative change over the entire year. Data collection and monitoring frequency should be appropriately selected to support the temporal and long-term evaluations.

4691 5.2.4.6 Project: Wastewater Recycling

While this project requires time consuming permitting and coordination with regulatory agencies as well as significant infrastructure installations it will be helpful in keeping Chico’s GW demand from expanding along with the urban development that is anticipated. Focusing purple pipe infrastructure on athletic field irrigation is a good target during dry seasons.

4722 5.2.4.7 Project: Community Water Education Initiative

A population that is well informed on watershed health, water use conservation and water policy is an excellent education goal. This project should identify regional responsible water use and climate responsive flexibility. The political science portion should dive into the history of California water policy; how it has shaped regional water infrastructure and the need for local vigilance in defending the hydrologic balance from insatiable demand from unfettered urban and agricultural expansion south of the Delta.

4768 5.2.4.8 Project: Rangeland Management and Water Retention

4802 5.2.4.9 Project: Fuel Management for Watershed Health

4833 5.2.4.10 Project: Removal of Invasive Species

Investments in the health of ecosystems that provide the water recharge for the Tuscan Aquifer System have been, like in the rest of the Sierra Cascade watershed, unwisely underfunded. An excerpt from the Sierra Nevada Ecosystem Project lays out the imbalance of resource extraction vs reinvestment. These projects would begin to address that imbalance.

“Based on estimates of direct resource values as one input (not the total revenue produced by resource dependent activities), the Sierra Nevada ecosystem produces approximately \$2.2 billion

worth of commodities and services annually. Water accounts for more than 60% of that total value. Other commodities [timber and grazing] account for 20% as do services.

“Public timber and private recreation are the largest net contributors of funds to county governments both in total dollars and as a percentage of their total value. Around 2% of all resource values are presently captured and reinvested into the ecosystem or local communities through taxation or revenue sharing arrangements. The declining status of some aspects of the Sierra Nevada ecosystem suggests that this level of reinvestment is insufficient to ensure sustainable utilization of the ecosystem.”

https://pubs.usgs.gov/dds/dds-43/VOL_III/VIII_C23.PDF

4870 5.2.4.11 Project: Surface Water Supply and Recharge While it is suggested that these projects will require a SWRCB permit; CEQA and others the State is on a path of “streamlining and acceleration of managed aquifer recharge and groundwater banking permitting processes” and to “Streamline groundwater substitution and water transfer permitting and approval processes to optimize the economic value of groundwater”.

<https://data.ca.gov/dataset/californias-groundwater-update-2020-bulletin-118/resource/94f3a5f6-23f3-4aec-ab84-b546bf211bab>

It is unclear if the legal and environmental consequences of this project will be adequately considered. The preservation of undisturbed critical vernal pool habitat is an ecological priority in some of the presumed areas of inundation.

4973 5.3.4 Landscape Ordinance

4980 5.3.5 Prohibition of Groundwater Use for Ski (Recreational) Lakes

These two common sense regulations would help meet our goals.

4984 5.3.6 Expansion of Water Purveyors’ Service Area

Assuming that this is exclusively for residential development it is critical that service area expansion does not stimulate urban sprawl that intrudes on either green-line or gold-line open space.

4990 5.3.7 Groundwater Allocation

The consideration of groundwater allocation must be scientifically connected to the actual cause of failure to achieve sustainability goals by 2042. If cross-boundary water flows are causing declining levels in up-gradient portions by extractions in the down-gradient portion of the shared regional aquifer system, there must be well designed/implemented monitoring/modeling systems in place that have the confidence of all involved.

5005 5.4 Data Collection

5006 5.4.1 County Contour Mapping

“As part of the efforts to collect the information necessary to fill the data gaps identified in Section 3, this project proposes to expand the existing monitoring program to include Butte, Glen, Colusa, and Tehama counties and conduct these groundwater elevation surveys in the spring, summer, and fall. The monitoring program would gather data used to produce groundwater contours and estimates of lateral and vertical flow direction and volume. Producing this data for the four counties will help to identify interbasin flow patterns and

influences on surface water flows and replenishment locations, thereby improving coordination between counties and water management decision-making.” This inter-basin effort must be implemented ASAP! A reliable inter-basin GW modeling is also at the top of the management list.

6. PLAN IMPLEMENTATION

5135 Table 6-5: Estimated Costs for Implementing Data Gaps

“Interconnected Stream Monitoring \$100,000 – \$250,000” As mentioned in previous comments the immediate implementation of a network of shallow monitor monitoring wells should be developed to detect changes in water levels over the shallowest portion of the aquifer. Baseline habitat monitoring is an important data collection objective because it allows for a better understanding of the existing water resource requirements of the native habitat and the evaluation of potential impacts associated with potential changes in water resource management practices. The long-term health of riparian vegetation, wetland species, and number of other native habitat are commonly associated with maintaining a minimum range of groundwater levels. Limiting the data gap to Interconnected Stream Monitoring would leave out GDEs that are outside of designated riparian zones. The shallow aquifer has an important role to play in keeping deep rooted trees, including the large trees in the Chico Urban Forest, that survive the regional dry months without supplemental irrigation.

The USDA also recognizes that Urban Forests such as exists in Chico and other Butte County towns provide a range of valuable ecosystem services. I posit that the groundwater dependent trees of our towns ARE ecosystems. Many environmental challenges are exacerbated within the urban landscape, such as stormwater runoff and flood risk, chemical and particulate pollution of urban air, soil and water, the urban heat island, and summer heat waves. Chico’s urban forest canopy mitigates these challenges. Research shows that urban trees are integral to the environmental quality of cities and towns.

In April of 2007 Butte County resolved to adopt an oak woodlands management plan.

“Butte County supports significant acreage of oak woodland habitat. The historical importance of oaks is apparent in the names of towns, cities, streets and residential complexes throughout California. Butte County’s oak woodlands enhance the natural and scenic beauty of the area, provide forage and shelter for more than 300 species of wildlife, facilitate nutrient cycling, moderate temperature extremes, reduce soil erosion, sustain water quality and increase the monetary and ecological value of property.”

http://www.buttecounty.net/Portals/10/Docs/Planning/Projects/OakWoodland/Chapter53_ButteCounty_OakWoodlandMitigationOrd_2018-10-29.pdf?ver=2018-10-29-165211-350

Water Code § 113: “It is the policy of the state that groundwater resources be managed sustainably for long-term reliability and multiple economic, social, and environmental benefits for current and future beneficial uses.”

5253 6.7 Interbasin Coordination

5271 1. Information Sharing

“This will continue throughout GSP implementation and may include:

- 1. Inform each other on changing conditions (i.e., surface water cutbacks, land use changes, policy changes that inform groundwater management)*
- 2. Share annual reports and interim progress reports*
- 3. Share data and technical information and work towards building shared data across and/or along basin boundaries (e.g., monitoring data, water budgets, modeling inputs and outputs, and Groundwater Dependent Ecosystems)”*

Information Sharing must include the water-market/emergency GW pumping volumes/locations/timing that members of the North Sac River Corridor group intend to implement and a report on the final v/l/t of these extra demands on the shared aquifer system. These extra pumping demands are not unprecedented and have become a routine component of California’s plan to use the Northern Sacramento Valley as a “reliable” source of supply.

Butte County is on the verge of conducting a Drought Impacts Analysis Study that will evaluate the numerous 2021 Water Transfer Programs in Northern Sacramento Valley including the Supplemental Groundwater Pumping Operations. The study portends to accomplish an evaluation of cumulative impacts of programs on water supplies and demands in the inter-basin, but focus on the Vina Subbasin"

https://buttecounty.granicus.com/MetaViewer.php?view_id=2&clip_id=1006&meta_id=157029
pdf Pg 42-43

The report will include a brief description of the programs, amount of water transferred, recipient of water, whether surface water or groundwater substitution is utilized, destination of transferred water, etc. including maps. This report should be conducted every year, funded by SGMA interbasin coordination parties and be included in the VGSA Annual report submitted by April 1 for the prior year’s activities.

5295 3. Coordinate on mutually beneficial activities

GSA that overlies the Tuscan Aquifer Formation should provide cooperative funding for mutually beneficial watershed management in the recharge areas located in the foothills east of the valley floor.

5314 5. Issue Resolution Process

“Vina Subbasin will pursue development of an issue-resolution process with neighboring subbasins in the North Sac River Corridor group.”

This single sentence description of the process to identify and resolve “issues” belies the potential for regional conflict over water management issues. The drama surrounding the nascent Tuscan Water District and the unpopular “Operational Range[s]” proposed in the DVGSP are examples of “issues” that have already emerged in this process. Conflict arising from expanded GW demand in the North Sac River Corridor group are being litigated between stakeholders and agencies. Achieving sustainability requires local agencies, stakeholders, and water users to make many difficult and potentially contentious decisions. These decisions are prone to conflict, particularly when pumping restrictions are viewed as infringing on property rights, or when fees are charged to support local management. Newly formed GSAs have additional layers of potential conflict. Questions regarding authority, streamlined legal and regulatory timelines, a lack of existing precedents and the need to represent agency and constituent interests have the

potential to exacerbate conflicts under SGMA. In some cases, where authoritative interpretations of legal authority and limits have not been established yet, litigation may be necessary and warranted. The State prefers the Northern Sacramento Valley to quietly comply with the myth that this region is a source of “surplus” water that can peacefully serve the accelerating water market through conjunctive-use water banking. However, it is likely that conjunctive-use water banking would degrade the groundwater basin and groundwater users who are not involved in conjunctive use but are reliant on the same groundwater basin.

Chapter 4: MONITORING NETWORKS

4218 Well “Construction Data – Well data such as perforation depths, construction date, and well depth was considered for selection.” Many of the selected wells do not meet the above criteria for selection: 4262 Table 4-5. Groundwater Levels RMS Well Construction Details

North MA: 3/6 of the wells do not have listed screen intervals. This makes it difficult to know what layer of aquifer is being monitored. Scientifically constructed multi-completion wells with defined screen depths/elevations is needed. The other 3 have screen intervals ranging from about 70’ to almost 500’. While this type of well construction is suitable for production it is unsuitable for transparent depth/elevation monitoring of the aquifer system.

Chico MA The well depths are undefined as are the screen depths. There is a notable lack in monitoring the shallow aquifer that supports the unirrigated Chico Urban Forest.

In summary:

The VGSP must strive to develop and use the best modeling/monitoring processes that recognize the influence of the upland recharge area and the downslope aquifer extraction that influences the ability of this GSA to achieve a robust sustainability goal that does not collapse during the inevitable dry periods that the historic record reveals and the climate destabilization models predict. The hydrologic and geologic science used must not be cast aside by the political science that drives California Water Policy that views the Butte County as an underutilized export source that can be “exercised” by conjunctive water banking. The environment, the urbanites and the rural community require a reliable water table that can’t be displaced, even during consecutive dry years.

FROM: Holly Dawley, GCID Water Resources Manager

SUBJECT: Support for Groundwater Sustainability Plans and Concern about Groundwater Surface Water Interactions

Glenn-Colusa Irrigation District (GCID) is located in the heart of the Sacramento Valley; we are the largest and one of the oldest diverters of water from the Sacramento River. GCID diverts water from the Sacramento River through a 65-mile long irrigation canal into a complex system of nearly 500 miles of laterals. The water is delivered to more than 1,200 families who farm approximately 141,000 acres of valuable, productive agricultural land. More than \$270 million of agricultural products are produced annually on Glenn-Colusa Irrigation District farms, helping to sustain an estimated 12,000 jobs in the region. GCID is also the sole source of surface water deliveries for three wildlife refuges – the Sacramento, Delevan and Colusa National Wildlife Refuges that comprise over 20,000 acres of critical wildlife habitat. Winter water supplied by GCID to thousands of acres of rice land also provides a rich oasis for migrating waterfowl.

GCID is an active member of the Colusa Groundwater Authority, the Glenn Groundwater Authority, and the Corning Subbasin Groundwater Sustainability Agency.

Support for Groundwater Sustainability Plans

GCID appreciates the opportunity to provide comment to your agency for Groundwater Sustainability Planning in the Sacramento Valley (Valley). As a member of three Groundwater Sustainability Agencies (GSAs) within the Valley, GCID staff have valued our participation in the development of two Draft Groundwater Sustainability Plans (GSPs) and support a collaborative approach to management across a shared resource. We support the adoption of the GSPs by each of the GSAs to meet the January 31, 2022, deadline and we look forward to continued participation during implementation.

Concern about Groundwater Surface Water Interactions

While we support the adoption of the GSPs, this communication serves as a formal written comment to highlight and express a particular area of concern that could lead

to the development of an incomplete decision framework and compromise the stability afforded to groundwater users in the various Sacramento Valley subbasins and more specifically to surface water users and senior water right holders which includes our District. We are writing to express deep concern regarding the lack of consideration in the GSPs about stream-aquifer interactions and impacts from unrestricted groundwater pumping.

This year in response to historically dry conditions, GCID and our fellow Sacramento River Settlement Contractors (SRSCs) took a multitude of voluntary actions significantly reducing the supply to our water users. These actions collaboratively supported watershed objectives in the face of declining storage and identified environmental concerns. While GCID and its partners were working daily for months with Central Valley Project (CVP) operators and State resource agencies to reduce surface water use and stabilize flows in the Sacramento River to help with Delta outflows and environmental needs, groundwater pumpers accessed the resource unabated impacting the stream flows we were actively working to stabilize.

As a significant contributor to groundwater recharge within the Valley, we only utilize that resource in years of shortage. We contribute every year to over 100,000 acre-feet (*Colusa GSP Draft, Appendix 3D, pg. 27*) of groundwater recharge even in Shasta critically dry years. However, we only utilize the resource when our surface water supplies are diminished by drought. Even with all of our voluntary surface water reductions in 2021, we only utilized 20,000 ac-ft of groundwater, while taking over 20,000 acres of land out of production to balance our supply and demand.

According to the Draft GSPs for Vina, Butte, Corning, and Colusa Subbasins, current year estimates of groundwater pumping, summarized in the table below, are over 1 million acre-feet per year (ac-ft/yr) in the region that surrounds our District.

Table 1, Groundwater Pumping in Subbasins in and around GCID (TAF)

	Historical	Current	Future, No Climate Change	Future, 2030 Climate Change	Future, 2070 Climate Change
Butte^a	142.2	162.8	162.6	189.4	210.5

Notes

^aButte Groundwater Sustainability Plan, Public Review Draft, Section 2, pg. 2-65

^bVina Groundwater Sustainability Plan, Public Final Draft, Section 2, pg. 82

^cColusa Groundwater Sustainability Plan, Final Draft Report, Section 3, pg. 3-96

^dCorning Groundwater Sustainability Plan, Public Review Draft, Section 4, pg. 4-69

This groundwater pumping impacts groundwater storage as evidenced by declining groundwater levels and impacts surface-groundwater interactions as evidenced by decreased streamflow and more reaches becoming losing streams. These numbers

indicate a need to understand the origin of groundwater pumping and the potential impacts to the subbasins as water users pull from a shared resource. In looking at these pumping numbers, a particular concern that becomes palpable is that all the GSPs identify increased groundwater pumping which will result in groundwater storage impacts and will result in increased streamflow depletion.

After reviewing the documents, senior surface water rights holders and their operations seem to be a minor share of the use of the resource, but a significant contributor to the replenishment of the resource. We ask that as GSAs move from planning to implementation and continue to look for opportunities to leverage surface water over groundwater, you consider those members and partners with senior water rights and stable contracts that contribute to our shared aquifers and provide high quality environmental habitat. We look forward to better identifying and quantifying this benefit for the subbasins during implementation. Further, we ask that GSAs work with their County partners to consider land use planning and accountability.

Thank you for your consideration of these concerns. We urge you to consider language to address or at least acknowledge this issue in the GSPs. We look forward to working through this issue during implementation.

Hello -

I attended the public zoom meeting last night - 10/13. I am in agreement with those who spoke regarding the idea that the minimum threshold is too severe/low. That current suggested minimum threshold could easily present problems - and not only for those with wells. Plants and wildlife have to have accessible water. We need to preserve our urban forest and landscape and the integrity and beauty of our local region - all of which is linked to our groundwater levels and how they are accessed. Natural recharge takes time and we are in a drought period and global warming which threatens the ability to recharge an aquifer that is being extensively drained. Artificial recharging as a proposed possible option is not desirable and would become a giant legal circus.

I also would like to suggest that agriculture - our biggest user of the aquifer - be cut back to meet the need for water retention in the groundwater table. We, the residents, are modifying our usage and so should ag businesses.

Thank you -

Get Tough on Cutbacks & Conservation

I am so worried as I read through your Vina Draft GSP. So much manipulation of our water can't be good. I firmly believe that the more we mess with nature, moving our water here and there, the more damage we are creating. Please stop and reconsider that some of these damaging actions would be better achieved through conservation measures. It's time we all acknowledge the fact that there is less to go around, and we all need to cut back...especially the biggest users, agriculture. The pain of cutbacks must be shared proportionately.

Please prioritize and fund all of the proposed Conservation PMAs presented to the Vina GSA on 02 Sept 2021, including:

- Agricultural Irrigation Efficiency - mandatory
- Residential Conservation - mandatory
- Streamflow Augmentation - so good for the salmon!
- Extend Orchard Replacement - use this incentive now
- Water Recycling - make it happen asap
- Community Water Education Initiative Education and Outreach - mandatory
- Rangeland Management and Water Retention Conservation - mandatory
- Fuels Management for Watershed Health - mandatory
- Removal of Invasive Species Conservation - gradual
- Agricultural Water Allocations - phase in immediately - no pain no gain!

Please make these conservation actions mandatory where noted...NOT voluntary. A voluntary program is really an insult to the precious resource we are trying to save. Show us you are serious...because this is serious, including water allocations for large farmers.

As Amer Hussain discussed at the virtual public workshop, once a goal is set, it's awfully difficult for even the most severely over-drafted districts to reset those goals. There's too much push-back at that point. This plan needs to be tough on standards out-of-the-gate, and then ease up restrictions as we can see our plan is effective....not the reverse.

Respectfully,

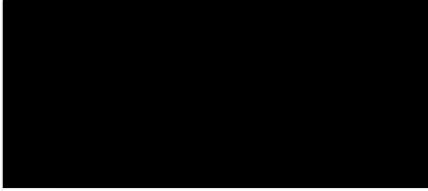

Pam Stoesser
Chico Resident

Very interesting concept...we already pay certain farmers not to grow. Why not try it to reduce demand on water? This could be one of the PMAs.

BY [IAN JAMES](#) STAFF WRITER OCT. 10, 2021 6 AM PT

BLYTHE, Calif. — Green fields of alfalfa and cotton rolled past as Brad Robinson drove through the desert valley where his family has farmed with water from the Colorado River for three generations. Stopping the truck, he stepped onto a dry, brown field where shriveled remnants of alfalfa crunched under his boots. The water has been temporarily shut off on a portion of Robinson's land. In exchange, he's receiving \$909 this year for each acre of farmland left dry and unplanted. The water is instead staying in

Lake Mead, near Las Vegas, to help slow the unrelenting decline of the largest reservoir in the country.

Robinson and other growers in the Palo Verde Irrigation District are taking part in a new \$38-million program funded by the federal Bureau of Reclamation, the Metropolitan Water District of Southern California and other water agencies in Arizona and Nevada. The farmers are paid to leave a portion of their lands dry and fallow, and the water saved over the next three years is expected to translate into 3 feet of additional water in Lake Mead, which has [declined to its lowest levels](#) since it was filled in the 1930s following the construction of Hoover Dam.

“Honestly, I think I could make more money farming. But for the sake of the Colorado River, I think it’s the right thing to do,” Robinson said. “The river’s going through a bad time right now.”

ADVERTISEMENT

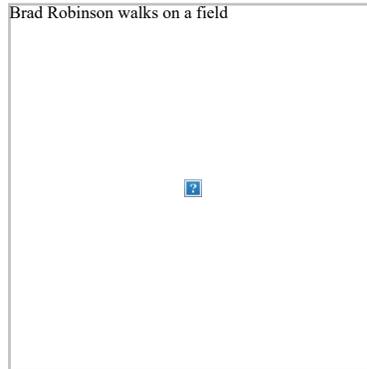

The arrangement is one of a growing number of programs that are springing up along the river to find water savings in agricultural areas. As reservoirs continue to decline, managers of water districts are looking to start or scale up similar land-fallowing programs in other areas, paying farmers not to farm temporarily on some fields and using the water to ease shortages.

Although the program in the Palo Verde Valley amounts to a minuscule boost for the shrinking Colorado River, the approach has been praised by water officials and local growers as one way of adapting to a river that yields less after years of severe drought [intensified by the warming climate](#). Robinson and other growers in Palo Verde say they hope their participation may encourage other water agencies to start similar initiatives and enlist more farmers to fallow land to help address the increasingly dire condition of the river.

Even as they take part in the program, some farmers remain suspicious of the powerful Metropolitan Water District and its intentions in their community. The MWD has bought thousands of acres of farmland around the town of Blythe over the years and has recently agreed to buy more land, eliciting fears among farmers that the water agency in Los Angeles could one day seek to take more water and dry up a larger portion of their valley.

“They’ve got a large portion of this valley. Why do they need more?” asked farmer Charles Van Dyke.

The Colorado River has long been chronically over-allocated, with so much water diverted to supply farms and cities that the river has for decades rarely reached the sea in Mexico. Most of that diverted water — [approximately 70%](#) — irrigates farmland, and much of that water flows to thirsty crops such as hay and cotton, which are [exported in large quantities](#).

ADVERTISEMENT

SINCE 2000, THE RIVER’S FLOW HAS SHRUNK DURING ONE OF THE DRIEST 22-YEAR PERIODS IN CENTURIES. SCIENTISTS HAVE DESCRIBED THE LAST TWO DECADES AS A [MEGADROUGHT](#), AND ONE THAT’S BEING WORSENERED BY THE HEATING OF THE PLANET WITH THE BURNING OF FOSSIL FUELS. RESEARCHERS HAVE WARNED THAT LONG-TERM “[ARIDIFICATION](#)” OF THE COLORADO RIVER BASIN MEANS THE REGION MUST ADAPT TO A RIVER THAT PROVIDES LESS WATER.

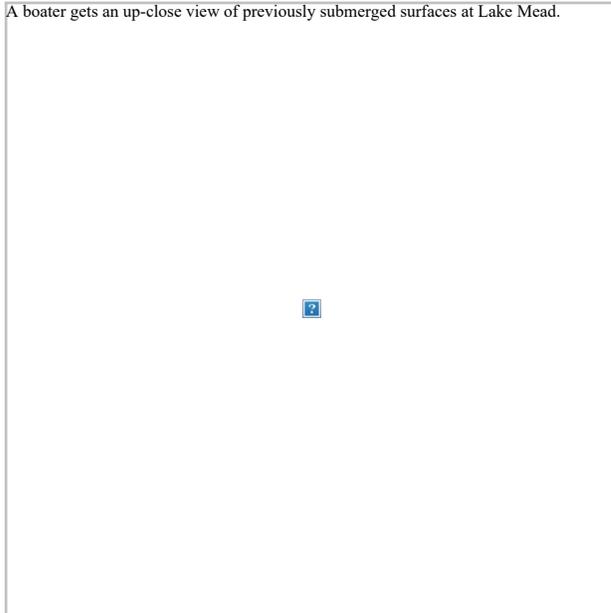

Supercharged by climate change, 'megadrought' points to drier future in ...

Global warming turned what would have been a moderate 19-year drought into one of most severe 'megadroughts' of ...

The water level in Lake Mead has declined 27 feet since January 2020. The reservoir now stands at just 34% of full capacity, placing it at a shortage level that will trigger mandatory water cutbacks next year for Arizona, Nevada and Mexico.

A boater gets an up-close view of previously submerged surfaces at Lake Mead.

A boater gets a view of previously submerged surfaces at Lake Mead. The lake's water level has dropped 27 feet since January 2020. (Allen J. Schaben / Los Angeles Times)

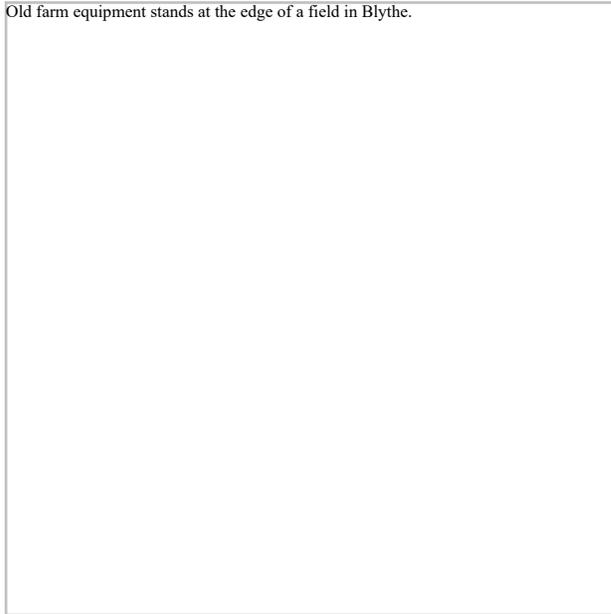

The lake's water level is projected to continue falling. The [latest estimates](#) from the federal government show the water in Lake Mead could drop an additional 30 feet by August 2023, a level that would require water cuts in California.

Since 2005, Robinson and other farmers in the Palo Verde Valley have left portions of their lands dry and unplanted under a [35-year deal](#) with the Metropolitan Water District, which has paid them more than \$180 million for water that was sent flowing through the Colorado River Aqueduct to cities in Southern California. Under the new deal, much of the water will instead be left in Lake Mead to try to reduce risks of the reservoir falling to critically low levels.

For managers of the MWD, the program offers flexibility, enabling them to pay for more land-fallowing in years when they need more water.

Each year, the MWD calls for a certain percentage of the valley's farmlands, up to a maximum of 28%, to be left fallow. Starting this year, the water from a portion of those lands is staying in Lake Mead.

Old farm equipment stands at the edge of a field in Blythe.

Old farm equipment stands at the edge of a field in Blythe. Since 2005, farmers in the Palo Verde Valley have left portions of their lands dry and unplanted under a 35-year deal with the Metropolitan Water District. (Luis Sinco / Los Angeles Times)

Similar programs have taken shape in several areas along the Colorado River.

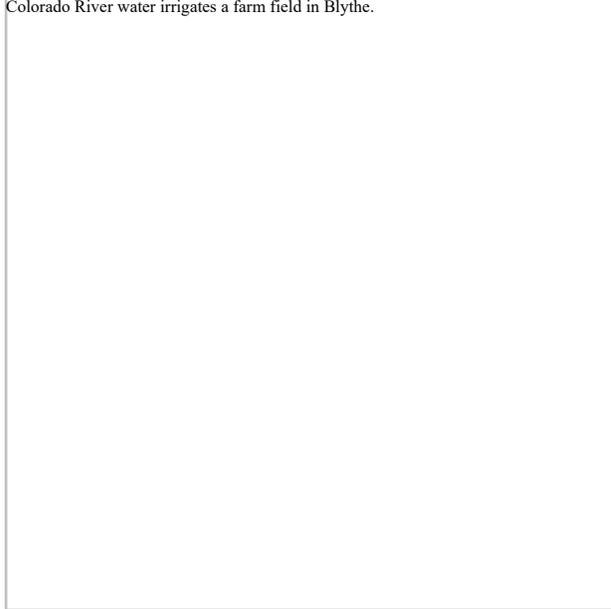

Last year, the MWD began paying farmers in the smaller Bard Water District not to plant water-intensive crops such as alfalfa [in the spring and summer](#), while they continue growing higher-value winter crops such as lettuce, broccoli and cauliflower.

ADVERTISEMENT

And the MWD's board is considering paying for [seasonal fallowing](#) under another [proposed agreement](#) with the Quechan Indian Tribe, whose reservation borders Arizona, California and Mexico, and includes farms that produce hay and vegetable crops.

Other initiatives are underway across the river in Arizona. Under agreements aimed at slowing the decline of Lake Mead, leaders of the Colorado River Indian Tribes have been [leaving some farmlands dry](#), and landowners in the Mohave Valley Irrigation and Drainage District have also been forgoing some water in exchange for payments.

Colorado River water irrigates a farm field in Blythe.

To support more fallowing of land in the Palo Verde Valley, the federal government is contributing half the funding — \$19 million — while the rest is coming from the Central Arizona Project, the Southern Nevada Water Authority and the MWD.

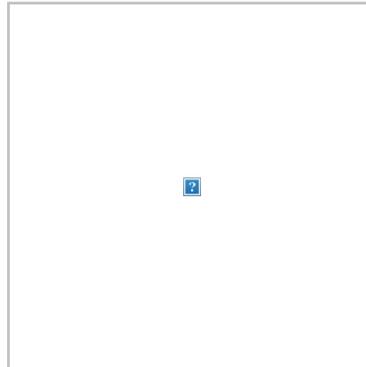

“This is just the beginning,” MWD General Manager Adel Hagekhalil said when the deal was announced in August. “We’re working to develop other innovative ideas to keep as much water as possible in Lake Mead.”

The program demonstrates how urban and agricultural water districts can work together to deal with shortages, said Bill Hasencamp, MWD’s manager of Colorado River resources.

“A lot of other states and other regions are looking to those programs as examples of what can be done elsewhere,” Hasencamp said. “We want to set a good example of how farmland can be productive in the era of shrinking water supplies.”

Reducing reliance on the Colorado River, he said, will require bigger water-saving efforts in cities and farming communities alike. The MWD supplies water to cities and water districts across Southern California that serve about 19 million people. The agency’s figures show that between 2011 and 2020, its water use declined about 7% — in part thanks to the lasting effects of conservation campaigns during the 2012-2016 drought.

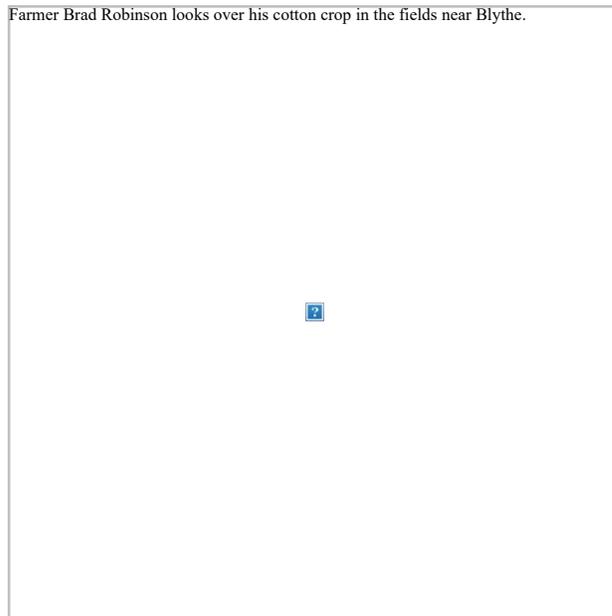

Because the latest estimates show Lake Mead is likely to continue declining, Hasencamp said, “we’re going to need to do more.”

Robinson, who is a board member of the Palo Verde Irrigation District, runs a family business that his grandfather founded in 1960. He now farms on about 3,200 acres around Blythe, including land he owns and leases. His fields produce cotton that is exported, alfalfa that is trucked to dairies in California, Bermuda grass that is baled to feed horses, and honeydews and other melons that are sold in supermarkets.

Farmer Brad Robinson looks over his cotton crop in the fields near Blythe.(Luis Sinco / Los Angeles Times)

“In a perfect world, a farmer wants to farm,” Robinson said. “But the reality of the situation is that we have a certain amount of population and people, and don’t have unlimited water. So ... the two sides are going to have to work together.”

The fields that are left dry are rotated every one to five years. And for the farmers, the cash payments provide a stable chunk of income that isn’t subject to price swings.

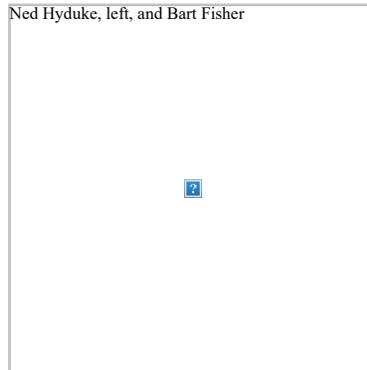

“We’re not getting rich off this. But it helps enough on the bad years,” when crop prices are low, Robinson said. “I’ve never laid anybody off because of the fallow program, and I never intend to do so.”

The program is far from a cure-all, and will need to be combined with other steps, said Chuck Cullom, manager of Colorado River programs at the Central Arizona Project. For example, water agencies in Arizona and Nevada have offered to invest in a proposed water recycling project in Southern California. And Cullom’s agency has been investing in testing water-saving irrigation technologies on Arizona farms.

“We all share the river. We all share risk,” Cullom said. “As the system becomes more vulnerable, we need all of the sectors to work together.”

The sorts of deals that temporarily leave farmland dry help by adding flexibility to the water system, but they also raise questions as the West grapples with the effects of climate change, including hotter, more intense droughts, said Newsha Ajami, director of urban water policy at Stanford University.

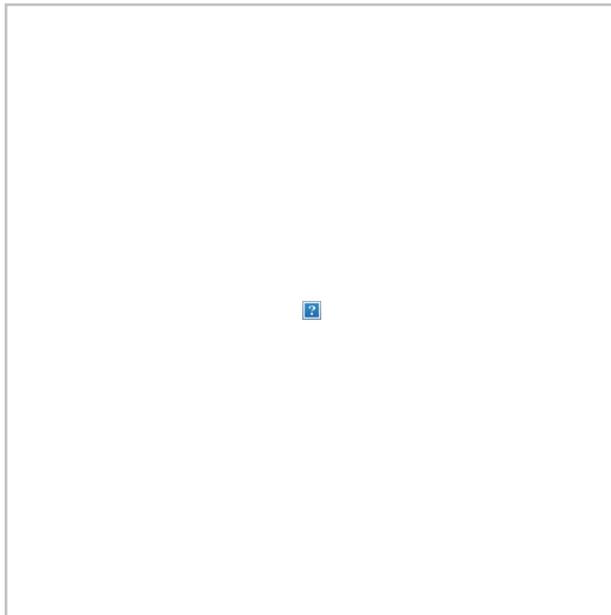

“If you’re experiencing drought after drought, and the droughts are getting hotter and drier, how long can you fallow land?” Ajami said. “I think it’s a Band-Aid. It’s a temporary solution to a more long-term problem we are having.”

Ned Hyduke, left, general manager of the Palo Verde Irrigation District, looks at a map of fallow farm fields around Blythe with Bart Fisher, the vice president of the irrigation district board.(Luis Sinco / Los Angeles Times)

Some Arizona farmers are already facing cutbacks in water deliveries from the river because they hold the lowest-priority water rights.

The farmers in Blythe, in contrast, hold some of the oldest water rights on the river, dating to 1877, when investor Thomas Blythe filed a claim to use water from the river. Based on that history, the growers of the Palo Verde Valley have a first-priority position among California water districts and would be among the last in line for cuts.

Farmer Bart Fisher shares a laugh with a worker while looking over seeding operations at one of his fields in Blythe. (Luis Sinco / Los Angeles Times)

“We should be the last ones to worry about water,” said Bart Fisher, a farmer who is vice president of the irrigation district board. “But if there’s no water in the river, it really doesn’t matter.”

Fisher, who runs a farming business that his grandfather founded in 1917, said even with such solid water rights, he and other growers have reason to be concerned about the river’s worsening crisis.

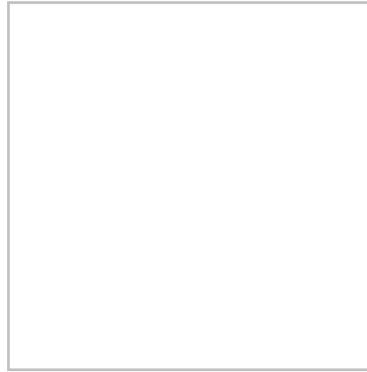

“It looks grim, actually. I was born in Blythe and I’ve been here all my life, and we’ve never been so threatened,” Fisher said, looking across a dry field where bits of garlic, remnants of the last harvest, were scattered in the soil.

He also grows broccoli, melons, wheat and hay, all of which rely on Colorado River water flowing through the canals.

“We could conceivably come to a place on the Colorado River where there is not water for anybody’s needs,” Fisher said. “We’re going to diminish reservoir levels to levels that we haven’t seen before, and the question then is, how do we respond?”

He said he hopes to see more deals emerge. If four or five other agricultural water districts pitch in, he said, their contributions could quickly add up to 10 feet or 15 feet of additional water in Lake Mead, which would make a big difference.

ADVERTISEMENT

A formerly sunken bench rests on the shore near the Hemenway Harbor launch ramp amid signs of the drought's effect on Lake Mead in Nevada.(Allen J. Schaben / Los Angeles Times)

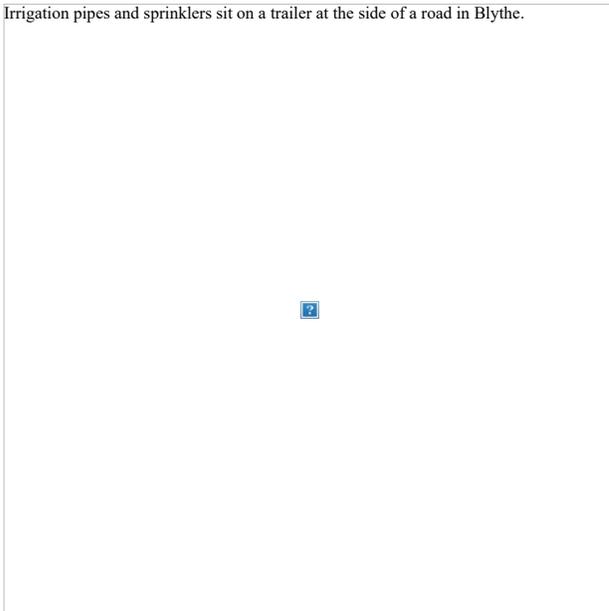

But even as Fisher and other farmers continue to participate in the MWD program and receive payments, they've also voiced concerns.

Under the deal, the MWD provided \$6 million to establish a locally run [community improvement fund](#) in Blythe that has provided grants and business loans in an effort to boost the local economy. Fisher said in retrospect, that one-time payment hasn't been enough.

Fisher drove down the main avenue, Hobsonway, where he passed shuttered businesses, including a motel, gas station, restaurant and several stores, all with boarded-up windows.

"I think we would do it a little differently today," Fisher said. "We would ask for more community support" from the MWD.

Irrigation pipes and sprinklers sit on a trailer at the side of a road in Blythe.

Irrigation pipes and sprinklers sit on a trailer at the side of a road in Blythe.(Luis Sinco / Los Angeles Times)

To the farmers' dismay, the MWD has bought large pieces of farmland in the Palo Verde Valley. The largest purchase, 12,000 acres in 2015, made the MWD the largest landowner in the irrigation district. The MWD says it now [owns about 29,000 acres](#) in the area.

The agency leases the land that isn't left dry to growers, offering reduced rent to farmers who plant crops that consume less water.

The problem with the MWD owning so much land, Fisher said, is that it ends up paying less to landowners in the valley. He said this deprives the area of approximately \$6 million to \$8 million annually that would otherwise be going to local businesses and fueling the economy.

"When [the MWD] follows their own land, they keep the money. So it doesn't make its way into our community. And it's a lot for a little community like this," Fisher said.

Worried by the MWD's land dealings, leaders of the Palo Verde Irrigation District [sued the agency in 2017](#), but then [dropped the lawsuit](#) in 2018.

ADVERTISEMENT

Recently, farmers objected when they learned of an MWD proposal to buy an [additional 702-acre property](#) from Cox Family Farms. The MWD board endorsed the purchase last month.

"We've told them that we think it's a very bad idea. It's bad for the community, and frankly, it's a predatory practice on their part," Fisher said. "It's just disappointing. It's sort of counter to the spirit by which we originally engaged with them to negotiate the fallow program."

At the MWD, however, officials [have discussed](#) the potential for additional purchases of farmland along the river in areas with high-priority senior rights as a way to reduce water use in agriculture and free up water for urban Southern California in dry times.

"It would allow us to play a long game with climate change by holding and leasing land for decades," Brad Coffey, manager of water resources management, said during a September [committee meeting](#).

Board members discussed whether to actively pursue future land purchases.

"I believe that if someone wants to sell us that land, that we should always answer the door," board member Larry Dick said. "We'll do it responsibly. We're not going to take that land and take it out of production forever."

Russell Lefevre, another board member, asked how the land purchases are viewed by the farmers.

"They did express concern about us buying land," said Hasencamp, MWD's manager of Colorado River resources. "We are working with them to try to alleviate some of those concerns."

Lefevre said he would support seeking out other land deals. He said he wonders "if we can move this methodology to other areas," such as the Coachella and Imperial valleys.

Thank you for considering our comments. Please make these comments part of the permanent public record.

I am concerned that the Vina GSA proposal doesn't go far enough in addressing sustainability. In contrast to the Vina GSA proposal, serious sustainability begins now, today. Not after we have pumped down our water table to dangerous depths. We need to seriously consider the direction we are heading with climate change and longer droughts. (Currently, next year is predicted to be a La Nina year refer to: <https://www.climate.gov/news-features/blogs/enso/july-2021-enso-update-la-ni%C3%Bl%a-watch>) which means next year will also likely be a drought). The current VINA proposal does not fully address the climate change reality and the prolonged droughts that accompany climate change.

The figures **on page 107** discussing water surface elevation shows that our water table is trending downward. It discusses the MO and MT. As defined here **the "operation range" is too deep**. With this proposed "operational range" there is the very real possibility that we could lose deep rooted trees, part of the Chico Urban forest. And also, and very seriously, we would lose too many domestic wells. **The operational range is much too deep and should be based on early levels (perhaps 2000 or 2005, at least 2010) before we pumped our aquifer to the current low levels.**

The current proposals heavily favour agriculture, which we all know is important, but equally important are our human community, our domestic wells and urban forest.

Has there been an Environmental Impact Report (EIR)? It would seem by substantially lowering the aquifer as proposed in VINA GSA we are affecting the local ecosystems as well as disrupting homeowners that use wells.

As said in comments by The Nature Conservancy,

"Potential Effects on Environmental Beneficial Users. SGMA requires that potential effects on GDEs and environmental surface water users be described when defining undesirable results. " Because effects on plants and animals are difficult and sometimes impossible to reverse, we recommend erring on the side of caution to preserve sufficient groundwater conditions to sustain GDEs and ISWs."

215.5 Says "Depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of surface water" must be seriously considered. I don't feel this has been adequately addressed. The report says in line 1740: "Relatively shallow groundwater in some areas of the subbasin support Groundwater Dependent Ecosystems and stream flows".

Thus, an EIR must be completed to understand the changes we are considering.

Thank you for addressing all of the above issues.

Sincerely,

Annette Faurote

Subject: comments | draft of Vina Basin Sustainable Groundwater Plan (SGP)
Date: Tuesday, October 19, 2021 11:02:56 PM

ATTENTION: This message originated from outside **Butte County**. Please exercise judgment before opening attachments, clicking on links, or replying.

Greetings colleagues. Below are my comments on the draft **Vina Basin Sustainable Groundwater Plan (SGP)**.

Thank you for the chance to contribute to these deliberations.

Sincerely, David Eaton (1080 East Lassen Avenue, Chico CA 95928)

COMMENTS

A. The “Measurable Objective” of 100 feet above mean sea level for the groundwater level is too LOW. The level of the past twenty years is already diminished from historical ‘normals’. The downward trend of the aquifer is evident in the materials provided.

We should not be depleting the aquifer *more* under the Draft SGP. Rather let us restore our aquifer to something resembling its historic average: let us say something like 140 feet above sea level.

B. The hydrological consultants cited estimate current pumping from the Vina sub-basin is 244k acre-feet per year, with all but 20k acre-feet for agricultural use. They estimate the current overdraft as about 10k acre-feet per year.

They then propose a **sustainable yield estimate at 233k acre-feet per year**. BUT this is **dangerously high**. This estimate is based on a recent period in which the aquifer has been in continued decline, and especially if recent and projected climatic trends continue, pumping at this level will bring **further reduction of the groundwater level**.

Please, **let us adopt a more conservative estimate for this sustained yield!** Using a modest ballpark figure of eighteen percent reduction in overall water use going forward, for example, as recently proposed by Governor Newsom, this could be about **200,000 acre-feet per year**.

Our groundwater is an irreplaceable, finite, and precious resource in our part of California. **Let us protect it effectively for generations to come.**

Thank you for your time and consideration! I look forward to learning what steps the members of your commission take to protect our shared resources, and in the meantime I thank you for your time and consideration.

Sincerely, David Eaton, PhD, MPH (Department of Anthropology, CSU Chico, email daeaton@csuchico.edu)

Subject: Comments on the Vina GSA Plan

ATTENTION: This message originated from outside **Butte County**. Please exercise judgment before opening attachments, clicking on links, or replying.

1. I remain concerned about the low levels of the MO's and the MT's in this plan.

This is not an aspirational plan and perhaps one that will further be a detriment to our shared aquifer. It is quite concerning that our beloved valley oaks and other heritage trees that are non-irrigated and are icons of Butte County are not being considered. There will be domestic well failures, chronic lowering of groundwater levels, die-off of groundwater dependent ecosystems.

2. I remain concerned about the 10,000AF water budget.

I would like to understand how this number was arrived at; I was told it was set via DWR's climate change model that actually predicts more rainfall in the upcoming years. I would like to see a drier model utilized as well as a wetter model. We should have at least two options but irregardless - a complete understanding as to how this water budget was set is needed.

3. I remain concerned about the undue influence of the Rock Creek Reclamation District on the Vina GSA Board when joint meetings are held.

The balance of power is clearly out of whack - leaning heavily toward industrial agriculturalists leaving 110,000 residents in the City of Chico with little to no voice and small farmers and domestic well owners with even less voice.

4. I remain concerned there are no "triggering" conditions to initiate conservation or demand reduction PMA's.

These need to be spelled out.

5. I remain concerned that the current drought has had no forbearance on this process.

We are told by technical staff and others that this need not be a concern since this is a long-range planning process yet it has been mentioned that we've already hit some of our lowest MT's. Is this true?

6. I remain concerned about the lack of current well data and the timeliness of the data.

There needs to be better coordination between environmental health, BC Water & Resource Conservation Department and DWR.

7. I remain concerned about the lack of current and fluid data regarding output of local water via groundwater transfers, riparian rights, SGMA credits, etc.

8. I remain concerned about the two consecutive dry years in a row to trigger MT's.

This seems irresponsible - particularly in a drought like we're in now. How many domestic wells have to go dry? Is this a loophole? Who is responsible for dry domestic well users or farmers? Who pays for this in the end if the Vina GSA sets MO's and MT's that are so low we begin to see negative effects?

9. I remain concerned about the one well for groundwater quality management in the North Vina subbasin.

Is this enough?

10. I remain concerned there is no mention of the groundwater markets being discussed up and down the state.

There is no analysis of this in the Vina GSP and it is critical to our area. It will be a reality to us in the north state to supply those in the San Joaquin Valley and Southern California with water. How will it affect pumping in our subbasins? How will water rights holders in Butte County participate? What are the possibilities? How will this affect our outflows and our modeling?

11. I remain concerned about the Vina SHAC process.

There have been at least two occasions where significant material was presented to the Vina GSA Board of Directors without review by the SHAC. Several members have expressed discontent with this process.

7. I remain concerned about the lack of current and fluid data regarding output of local water via groundwater transfers, riparian rights, SGMA credits, etc.

8. I remain concerned about the two consecutive dry years in a row to trigger MT's.

This seems irresponsible - particularly in a drought like we're in now. How many domestic wells have to go dry? Is this a loophole? Who is responsible for dry domestic well users or farmers? Who pays for this in the end if the Vina GSA sets MO's and MT's that are so low we begin to see negative effects?

9. I remain concerned about the one well for groundwater quality management in the North Vina subbasin. Is this enough?

10. I remain concerned there is no mention of the groundwater markets being discussed up and down the state. There is no analysis of this in the Vina GSP and it is critical to our area. It will be a reality to us in the north state to supply those in the San Joaquin Valley and Southern California with water. How will it affect pumping in our

subbasins? How will water rights holders in Butte County participate? What are the possibilities? How will this affect our outflows and our modeling?

11. I remain concerned about the Vina SHAC process.

There have been at least two occasions where significant material was presented to the Vina GSA Board of Directors without review by the SHAC. Several members have expressed discontent with this process.

As a participant in Vine GSA's. Groundwater Sustainability Plans (Plan) October 13, 2021 Zoom meeting I offer the follow:

Protecting residential wells from running dry should be a top concern of the GSA, yet the Plan actually sets acceptable percentages for their failures. This is unacceptable. Thereby, instituting across the board water conservation actions and raising the Plan's "minimum groundwater level thresholds" to protect residents and the environment must be facilitated. With water conservation plans and methods celebrating decades of use and success it is shocking and absurd that the GSA representatives seemed opposed in supporting them and were solely focused on the Plan.

I was disturbed by the GSA representatives inability to answer a question as to whether groundwater rights holders would have equal access to injected surface water into the aquifer. Clearly, the public is not properly informed on this important issue.

Finally, the public was left confused as to who could be in charge of handling future Plans and updates. It was said several times that residents would have a voice in future plans during review periods, however this would not be the case if a private water district should take over this duty and Institute a 1-vote per acre system. Knowing who and how a public trust resource is managed is essential to the public's rights and it should be mandatory that this be spelled out to current water right's holders.

Respectfully,
Nancy Gillard-Bartels
